WORKING PAPER NO. 01-2009

Greening Goliaths versus Emerging Davids – Theorizing about the Role of Incumbents and New Entrants in Sustainable Entrepreneurship

Abstract

This paper proposes a model of how incumbents and new entrants engage in sustainable entrepreneurship. We suggest that in the early stages of an industry's sustainability transformation, new entrants ('Emerging Davids') are more likely than incumbents to pursue sustainability-related opportunities. Incumbents react to the activities of new entrants by engaging in corporate sustainable entrepreneurship activities. While these 'Greening Goliaths' are often less ambitious in their environmental and social goals, they may have a broader reach due to their established market presence. This paper analyses the interplay between 'Greening Goliaths' and 'Emerging Davids' and theorizes about how it is their compounded impact that promotes the sustainable transformation of industries.

Keywords: Entrepreneurship, Corporate Sustainability, Incumbents, Start-ups

1 Executive summary

Global climate change and the accelerating depletion of natural resources are just two of several phenomena indicating that the world is not well aligned with the concept of Sustainable Development (Brundtland Commission, 1987). The severity of global sustainability challenges leads to an increasing awareness that incremental solutions will

not be enough to maintain critical levels of natural and social capital (Russo, 2003), and hence there is an increased interest in sustainable entrepreneurship as a phenomenon and a research topic (Cohen & Winn, 2007; Dean & McMullen, 2007). Sustainable entrepreneurship research has evolved from two separate research streams on environmental and social entrepreneurship (Zahra, Gedajlovic, Neubaum, & Shulman, 2009), and has traditionally focused on small firms, sometimes down to the level of the individual entrepreneur. This inclination to focus on sustainability-related start-ups and their founders is perhaps an adequate counter-trend towards the inherent large-firm focus in existing corporate sustainability literature. However, while their actions are important, there are arguably a number of limitations to the impact that small firms can have on the sustainable transformation of industries. Sustainability-related entrepreneurial initiatives within large firms, on the other hand, are also not free from challenges. By referring to the processes of "Emerging Davids" and "Greening Goliaths", this paper presents a conceptual framework that discusses the relative contributions of small and large firms to the transformation of industries towards sustainable development. In addition to discussing the relative strengths and weaknesses of "Davids" and "Goliaths", we also develop a model of how they interact over time, thereby showing that it is their compound impact that leads an industry towards sustainability. We argue that in the early stages of an industry's transformation towards sustainability, it is typically small firms and new entrants that stimulate disruptive sustainability innovation. Attracted by the early market success of Davids, Pioneer Goliaths follow up with corporate sustainability entrepreneurship initiatives of their own. Thanks to their larger scope, these initiatives take the sustainable transformation of an industry to the next level. Because of their

complementary skills and challenges with regard to sustainable entrepreneurship, a coevolution of "Emerging Davids" and "Greening Goliaths" is more likely to result in sustainability than either of the two alone.

Our conceptual framework and findings have important implications for research and practice, perhaps more so than ever in the light of the current confluence of the financial and climate crises. Just consider the example of the car industry: As demand for gas-guzzling vehicles has faltered and large incumbent car manufacturers are struggling to survive, it has become clear that there is a dire need for sustainable entrepreneurship. But where should policy makers focus their efforts in order to facilitate a sustainable transformation of the car industry - pushing towards "Greening Goliaths", hence funding for innovation within Detroit's incumbent firms? Or should they rather focus on supporting "Emerging Davids", as some of Silicon Valley's high-profile entrepreneurs such as Shai Agassi or Elon Musk, founder of Tesla Motors, suggest (Waters, 2008)? Rather than exclusively listening to the voice of incumbents (which is arguably a popular approach in politics) or putting all eggs in the basket of start-ups, policy-makers would be well advised to consider the specific strengths and weaknesses of both options and to pursue a portfolio that provides simultaneous incentives for Greening Goliaths *and* Emerging Davids. As for entrepreneurs in small and large firms, this paper helps them come to a realistic assessment of what their contribution towards the sustainable transformation of an industry can be, and where they should consider partnering with complementary counterparts. Finally, for researchers of sustainable entrepreneurship, we outline a number of specific suggestions for future research at the interface of Goliaths and Davids.

2 Introduction

Businesses in many industries are increasingly confronted with environmental and social challenges. Rather than just focusing on short-term profits, stakeholders expect firms to meet a triple-bottom line of economic, environmental and social value creation (Elkington, 1997). The increasing importance of sustainable development creates new risks, but also new opportunities for businesses. Reaping these opportunities requires firms to come up with innovative solutions for tomorrow's markets (Hart and Milstein 2003). There seems to be an increasing awareness that there is a business case for sustainable entrepreneurial initiatives, and achieving "green growth" (Ki-moon & Gore, 2009) is a popular theme in the political debate. But how does green growth come about? What does it take for sustainable entrepreneurs to blossom? And particularly, is sustainable entrepreneurship something that happens in large firms or small firms?

The aim of this paper is to provide a conceptual contribution to clarify the role of two different visions of sustainable entrepreneurship, which we refer to as 'Greening Goliaths' and 'Emerging Davids'. Our objective is to discuss the relative strengths and challenges of large and small firms in embarking on sustainable entrepreneurship, and to develop an evolutionary model of how their compounded impact promotes the sustainable transformation of industries.

The paper proceeds as follows. The following chapter 3 clarifies the terminology used in this paper and briefly introduces key concepts. Chapter 4 provides a review of existing

literature on sustainable entrepreneurship, as well as the two related concepts of environmental and social entrepreneurship. It ends with a review of studies at the intersection of firm size and (sustainable) innovation. Chapter 5 then includes the key conceptual proposition, and explores the interplay between 'Davids' and 'Goliaths'. Chapter 6 concludes the paper, provides suggestions for further research and highlights implications for entrepreneurs and policy makers.

3 Terminology

The notion of sustainable entrepreneurship is rather recent and its definition is still emerging. Dean and McMullen's focus on market failures in their definition of sustainable entrepreneurship as "the process of discovering, evaluating, and exploiting economic opportunities that are present in market failures which detract from sustainability, including those that are environmentally relevant" (Dean & McMullen, 2007). Cohen and Winn also stress the discovery of opportunity as essential when they posit that sustainable entrepreneurship research examines "how opportunities to bring into existence future goods and services are discovered, created, and exploited, by whom, and with what economic, psychological, social, and environmental consequences" (Cohen & Winn, 2007: 35).

This paper explicitly draws on the Schumpeterian (1962 [1934]) notion of entrepreneurship as an innovative process of creating market disequilibria (Eckhard & Shane, 2003; Shane & Venkataraman, 2000) which in turn lead to imitation. We thus

define sustainable entrepreneurship as the discovery and exploitation of economic opportunities through the generation of market disequilibria that initiate the transformation of a sector towards an environmentally and socially more sustainable state.

By linking sustainable entrepreneurship to the transformation of an industry towards sustainable development, we respond to Cohen and Winn's call for going beyond research on "corporate 'greening' initiatives and their impact on firm performance, [which] (...) is focused on incremental innovation (...)" (Cohen & Winn, 2007: 47). Our attention in this paper is primarily aimed at product innovation, although it might be interesting in the future to explore differences between product and process innovation in relation to sustainable entrepreneurship.

Since sustainable entrepreneurial opportunities are typically linked to market failures or externalities, exploiting these opportunities involves both market- and non-market strategies (Baron, 1995; Hillman & Hitt, 1999). We define non-market strategies as the set of activities that firms use to influence social, environmental and political stakeholders.

In this paper, we are suggesting that there are two different types of organizations that engage in sustainable entrepreneurship, namely "Davids" and "Goliaths" (see

). While inherently metaphorical, these terms shall be defined as precisely as possible in the current chapter. By Davids, we refer to small firms that tend to be recently founded and have a relatively small market share. In the context of sustainability, we are particularly interested in those among the larger population of small firms that explicitly

aim at providing not just economic value, but also social and environmental value. By Goliaths, we refer to large incumbent firms who tend to be older and have a relatively high market share.

Table 1: Characteristics of Davids and Goliaths

Criteria	Davids	Goliaths
Age	rather new	old, incumbent
Size	Small	large
Objective Function	social and/or environmental objectives at least as important as economic objectives	economic objectives dominating, social/environmental objectives complementary

Both the emergence of Davids as well as a process of "Greening Goliaths" can result in a transformation of an industry towards sustainability. We use the term "greening" in its colloquial sense. In public discourse "greening" is often used as a synonym for sustainable development. We do, however, stress that sustainable development should not be restricted to just environmental protection but needs to include the social and economic dimension as well. **Fejl! Henvisningskilden blev ikke fundet.** visualizes the key concepts that we are using in this paper and how they relate.

Figure 1: Emerging Davids and Greening Goliaths

Source: (Wüstenhagen, 1998)

Both Davids and Goliaths engage in sustainable entrepreneurship, but not all activities by Davids or Goliaths to improve environmental or social performance can be characterized as sustainable entrepreneurship. In line with our definition of sustainable entrepreneurship provided above, we use the term sustainable entrepreneurship to describe activities by small or large firms that represent disruptive, rather than incremental innovation. Goliaths routinely engage in incremental environmental or social innovation, e.g. through the introduction of sustainability management systems, eco efficiency or corporate social responsibility initiatives. In our terminology, those

activities would not qualify for the term (corporate) sustainable entrepreneurship. Equally, Davids who are active in a high-end environmental or social niche, but with no intention to broaden their impact on a wider market would be categorized as incrementally innovative and hence not sustainable entrepreneurs. These "bioneers" (Schaltegger, 2002) or "social bricoleurs" (Zahra et al., 2009) often come from the voluntary sector and tend to be opposed to consumerism and growth. They worry that mainstreaming requires them to abandon their ideals.

4 Literature Review

4.1 Sustainable Development and Entrepreneurship

The term sustainable development ties together concern for the carrying capacity of natural systems with the social challenges facing humanity (Brundtland Commission, 1987; Keating, 1993). As early as the 1970s, sustainability was employed to describe an economy "in equilibrium with basic ecological support systems" (Stivers, 1976: 187).

Traditionally ecologists have pointed to the “limits of growth” (Meadows, Meadows, Randers, & Behrens, 1971; Meadows, 1977; Meadows, Meadows, & Randers, 1991) and demanded a “steady state economy” (Daly, 1973, 1991) in order to address environmental concerns. The sustainable development debate is based on the assumption that societies need to manage three types of capital (economic, social, and natural), which may be non-substitutable and whose consumption might be irreversible (Dyllick & Hockerts, 2002).

Daly (1991), for example, points to the fact that natural and social capital can not necessarily be substituted by economic capital. While it is possible that we can find ways to replace some natural resources, it is much more unlikely that they will ever be able to replace eco-system services, such as the protection provided by the ozone layer, or the climate stabilizing function of the Amazonian forest. In fact natural capital, social capital and economic capital are often complements. A further obstacle to substitutability lies also in the multi-functionality of many natural resources. Forests, for example, do not only provide the raw material for paper (which can be substituted quite easily), but they also maintain biodiversity, regulate water flow, and absorb CO₂ (Siebenhüner, Dedeurwaerdere, & Brousseau, 2005).

Another problem of natural and social capital deterioration lies in their partial irreversibility. The loss in biodiversity, for example, is often definite when a tipping point is reached. The same can be true for cultural diversity. Moreover, the depletion of natural and social capital may have non-linear consequences. Consumption of natural and social capital may have no observable impact until a certain threshold is reached. A lake can, for example, absorb nutrients for a long time while actually increasing its

productivity. However, once a certain level of algae is reached lack of oxygen causes the lake's ecosystem to break down all of a sudden.

If the degradation of natural and social capital has such important consequence the question arises why action is not taken more systematically to alleviate it. Cohen and Winn (2007) point to four types of market failure as possible explanations: Firstly, while the benefits of natural or social capital depletion can usually be privatized the costs are often externalized (i.e. they are born not by the party responsible but by society in general). They add that many times natural capital is also undervalued by society since we are not fully aware of the real cost caused by the depletion of natural capital. Information asymmetry is a third reason identified to cause natural and social capital depletion. Often the link between cause and effect is obscured, thus making it difficult for actors to make informed choices. Cohen and Winn close with the realization that contrary to economic theory many firms are not perfect optimizers. They postulate that firms often do not optimize resource allocation because they are caught in a business as usual mentality.

As awareness of sustainable development grows in society, the market failures discussed by Cohen and Winn are likely to diminish. For example, they expect that society will increasingly realize the value of natural and social resources boosting their economic value. As a result firms will have to internalize costs that formerly have been borne by society. This change is called the sustainability transformation of an industry (Dyllick, 1999; Dyllick, Belz, & Schneidewind, 1997).

4.2 From Social and Environmental Entrepreneurship to Sustainable Entrepreneurship

While social and environmental aspects of Sustainable Development are inextricably linked, a large part of the academic literature on sustainability entrepreneurship deals with either one or the other. A first group of authors put environmental innovation at the heart of their work. These literature contributions have coalesced around the theme of eco-innovation, which more recently has spawned the subdiscipline of clean-technology venturing. A second line of publications deals with innovations aiming at social improvements (e.g. health, education, community development). Here the term social innovation can refer to product innovations with a social purpose. A subgroup of these types of innovations concerns “Base of the Pyramid” thinking. Social innovation is also used to refer the process of starting and improving social enterprises.

The notion that sustainable development drives disruptive innovation (Christensen 1997) has come quite naturally to the sustainability debate (Cohen & Winn, 2007; Hockerts, 1999, 2003; Wüstenhagen, Hamschmidt, Sharma, & Starik, 2008). Sustainable entrepreneurship has been proposed as a "breakthrough discipline for innovation" (Fussler, 1996), as a "source of creative destruction" (Hart & Milstein, 1999: 23), as well as the beginning of the "next industrial revolution" (Braungart & McDonough, 1998: 82; Lovins, Lovins, & Hawken, 1999: 1; Senge & Carstedt, 2001: 24). From this has emerged a large number of publications advancing tools for furthering the creation of new markets through environmental innovation (Fussler, 1996; Kolk & Pinkse, 2004; McDonough & Braungart, 2002b, 2002a).

In his influential book on Eco-Innovation, Fussler (1996) states that a majority of today's firms is not actively pursuing sustainability entrepreneurship as a strategy to create market share. However, he does not believe that this "innovation lethargy" (Fussler, 1996: 9) will persist in the years to come. Using a number of anecdotal case studies he shows that innovative firms can succeed in driving ecological innovation profitably, not by following current customer demand but by creating future market space. This notion that firms can actively transform market structures to make them more conducive to ecological innovation is also proposed by Dyllick (1999). Schaltegger and Wagner (2008) even propose that the ambition to transform an industry is a defining element of sustainable entrepreneurship, implying that sustainable entrepreneurial firms do not only see sustainability as central to core business activities, but at the same time aim for mass market transformation beyond the eco-niche (Villiger, Wüstenhagen, & Meyer, 2000). On the social side of sustainability entrepreneurship the term "corporate social innovation" was first introduced by Rosabeth Moss Kanter (1999: 125) who argues that firms should use social issues as a learning laboratory for identifying unmet needs and for developing solutions that create new markets. She describes, for example, BankBoston's effort in setting up a Community Bank, which has eventually evolved into a new market for the bank. More recently Patrick Cescau, CEO of Unilever, has defined corporate social innovation as a way of finding new products and services that meet not only the functional needs of consumers for tasty food or clean clothes but also their wider aspirations as citizens. (cited in Webb, 2007)

An important subtheme of corporate social innovation is the focus on low-income markets. Prahalad and Hart (1999) talk in this context of the potential of the bottom or

base of the pyramid (BOP) or a source for "the great leap downward" (Christensen, Craig, & Hart, 2001: 92). The BOP premise is that by focusing on the unmet needs of low-income populations (i.e. those who are situated at the base of the wealth pyramid) firms can create profitable markets while also helping the poor address some of their most urgent needs (Christensen et al., 2001; Prahalad & Hammond, 2002; Prahalad & Hart, 2002). Prahalad's most notable assumption is that BOP markets have to pay a "poverty premium" (Prahalad & Hammond, 2002). This means that many poor have to pay more for products and services such as food, water, medication, credit, or telecommunication, than their middle or upper class compatriots. By using BOP thinking MNCs are believed to better target their design as well as improve the distribution so as to bring down the poverty premium.

In parallel to the corporate version of social entrepreneurship described above there is also a growing literature on start-up ventures motivated by social innovation. The concept of social entrepreneurship has emerged in the late 1990s (Bornstein, 1998; Boschee, 1995; Brinckerhoff, 2000; Dees, 1998a, 1998b; Dees, Emerson, & Economy, 2001a, 2001b; Drayton, 2002; Henton, Melville, & Walesh, 1997; Warwick, 1997). However, it has only recently reached the academic debate (Haugh, 2006; Hockerts, 2007; Light, 2006; Mair & Marti, 2006; Mair, Robinson, & Hockerts, 2006; Nicholls, 2006; Perrini, 2006; Robinson, Mair, & Hockerts, 2009).

Ultimately, sustainable entrepreneurship is about a combination of economic, social and environmental value creation. Such integrated views of sustainable entrepreneurship are only starting to emerge in the academic literature (Cohen and Winn 2007, Dean and

McMullen 2007, Schaltegger and Wagner 2008), which after all is the rationale for this special issue of Journal of Business Venturing.

4.3 Firm size and the diffusion of sustainable innovation

Whether large or small firms are more likely to pursue sustainable entrepreneurship is a question that has rarely been asked in the academic literature. In terms of entrepreneurship more broadly, however, the influence of firm size on innovation is almost a classic theme. On the one hand using an economies of scale argumentation large firms have been hypothesised to be more innovative because of their broader resource base which allows them to pursue higher levels of research and development (R&D) (e.g. Galbraith, 1956; Kamien & Schwartz, 1982; Schumpeter, 1942). In his meta-analysis of 20 prior studies, Damanpour (1992) finds that the positive relationship between size and innovation is stronger in manufacturing than service industries and relates more to innovation implementation than initiation. A contrasting, but equally popular view in the literature is that small firms are more flexible and therefore avoid some of the organizational inertia that characterizes large firms, leading to a negative correlation between firm size and innovation (Acs & Audretsch, 1987, 1988; Audretsch & Acs, 1991; Stock, Greis, & Fischer, 2002).

The innovation management literature has highlighted the particular challenges that large incumbent firms face in the light of radical innovation (Christensen, 1997; Leifer, 2000), and suggested ways to overcome those challenges such as the creation of a "radical innovation hub" (Leifer, 2001) or cooperation with outside venture capitalists (Chesbrough, 2000). Despite specific opportunities to improve innovation management

in incumbent firms, Burgelman points out that there are inherent tensions in marrying large corporations with radical innovation, and that organizational attempts to overcome the challenges, such as new venture departments, will remain “a design for ambiguity” (Burgelman, 1985: 52).

One way to resolve the controversy around firm size and innovation is to move from a static to a dynamic perspective. Innovation scholars with an evolutionary economics perspective have highlighted that large and small firms play differing roles in different phases of industry evolution. As Utterback and Suarez (1993) point out, the technological trajectory of an industry is characterized by discontinuities, which lead to the emergence of a technological paradigm change (Nelson & Winter, 1982). When a new technological paradigm emerges, this results in the creative destruction (Schumpeter, 1962 [1934]) of existing competencies, thereby improving the selection environment for small entrepreneurial firms and other industry outsiders who are more flexible to pursue new opportunities without the liabilities of existing assets (Tushman & Anderson, 1986; Utterback, 1994). In terms of industry development, a technological paradigm change is usually characterized by a high degree of variation, i.e. a large number of new entrants experimenting with new product designs (Metcalf, 1994; Utterback & Suárez, 1993). As soon as a dominant design (Utterback & Abernathy, 1975) emerges, there is a shift from variation to selection, i.e. industry consolidation and an increasing number of exits.

When it comes to the diffusion of sustainable innovation, firms are faced with additional challenges because of a double externality problem (Rennings, 2000). As in the case of conventional innovation, there is an externality in that technological spill-over prevents the innovator from appropriating the full value of an innovation. In the case of

sustainable innovation, however, there is a second externality, namely the lack of internalization of environmental or social cost for incumbent technologies. The presence of external costs has two important effects: First, it reduces the relative (private) benefit of sustainable innovation for customers. Firms who want to successfully commercialize sustainable innovation therefore need to make special efforts in convincing customers that the product they are offering is not just good for society, but also good for them. Second, the flip side of this is that government policy is playing a more important role in commercializing sustainable innovation, because it is the role of government to internalize external cost through taxation or other economic policies. Therefore, innovating firms in the realm of sustainability need to understand government policy more so than their conventional counterparts, pointing to the importance of non-market strategies in the context of sustainable entrepreneurship.

5 Emerging Davids, Greening Goliaths, and their Interaction

This paper conceptualises the notion that starts-ups and market incumbents each have a role to play in the transformation of industries towards sustainable development. We can observe that more and more sustainable ventures emerge as an industry is increasingly pressured to adopt sustainable development. These ‘Emerging Davids’ usually display a high level of environmental and/or social performance that is attractive to a select number of consumers who are very concerned about sustainability issues. However, often Davids fail to attract a broader mass market.

Market incumbents on the other hand tend to focus initially on sustainability communication and accounting systems (e.g. Beske, Koplin, & Seuring, 2006; Burritt & Saka, 2006; Halme & Huse, 1997; Morsing & Schultz, 2006; Seuring, 2004). While these may lead to gradual improvements, they rarely go beyond incremental innovation. However, faced with growing competition from ‘Emerging Davids’, incumbents increasingly engage in their own form of corporate sustainable entrepreneurship. These ‘Greening Goliaths’ promise to achieve a broader impact, since they have the potential to reach out to a mass market audience (Villiger et al., 2000).

Extant literature on sustainable entrepreneurship has tended to cover either incumbents or new start-ups. There is very little discussion of the interplay between these two players when they engage in sustainable entrepreneurship, with the exception of a few empirical cases that are summarized in Table 1. These contributions touching upon the David/Goliath theme tend to discuss anecdotal evidence from four main substantive areas: fair trade, organic food, green electricity, and microfinance. In our subsequent theorizing we will draw on this body of literature aiming to synthesize from it a more encompassing set of insights.

Table 2: Extant literature discussing examples of Emerging Davids and/or Greening Goliaths

Author	Sector	Area	Contribution
Davies & Crane (2003)	Fair Trade	UK	Documents tensions a fair trade start-up experiences with its grassroot ideals as it competes increasingly with incumbents.
Hockerts (2006a)	Fair Trade	UK	Describes how fair trade emerged from the voluntary sector, followed by social business start-ups; Later retailers and food producers launch own label fair trade products.
Nicholls & Opal (2005)	Fair Trade	UK	Compares mainstream retailers and fair trade start-ups and their strategies for increasing the fair trade market share.
Latacz & Foster (1997)	Organic Food	Germany and UK	Discusses the short-comings of the niche marketing structures for organic food in Germany and the UK. Speculates about the role of mainstream supermarkets.
Villiger (2000)	Organic Food	Switzerland	Organic food initially offered by smaller wholefood stores and grassroots initiatives, large retailers followed at varying speed.
Dimitri & Greene (2006)	Organic Food	USA	Organic food previously sold through dedicated natural food stores; since the year 2000 conventional supermarkets have taken over as the primary sales channel.
Jacobsson & Johnson (2000)	Renewable Energy	Europe	Examines the diffusion of renewable energy technologies and the role played by “prime movers”.
Bird et al. (2002)	Renewable Energy	International (10 countries)	Green electricity start-ups relatively unsuccessful due to customer inertia, yet growing competitive threat due to market liberalisation causing proactiveness of incumbents.
Wüstenhagen et al. (2003)	Renewable Energy	Switzerland	Green electricity initially offered by smaller utilities and grassroots new entrants, large utilities followed at varying speed.
Stenzel and Frenzel (2008)	Renewable Energy	Germany, Spain, UK	Incumbents initially reluctant to renewable energy (except in Spain); co-evolutionary processes between firms, their technological strategies and the regulatory environment occur.
Baydas et al. (1997)	Microfinance	Developing countries	Discusses how commercial banks face challenges when they enter the area of microfinance and its development agenda.
Campion & White (1999)	Microfinance	Developing countries	Describes how microfinance NGO become more and more like incumbents as they are transformed into regulated financial institutions.
Christen & Cook (2001)	Microfinance	Latin America	Discusses how microfinance start-ups are transformed by commercialisation and the resulting risk of mission drift.
Cull et al. (2007)	Microfinance	Developing countries	Discusses the trade-offs between profitability and fighting poverty faced by microfinance banks.

5.1 Emerging Davids: The Emergence of Sustainability Start-ups

New start-ups are unencumbered by the incumbents' fear of cannibalizing the market share of their prior products. Being often run by idealists, sustainability start-ups are less likely to be caught in a specific technological mindset and more prone to try out innovative approaches. Furthermore, given their status as newcomers they are more credible when claiming to be part of the solution rather than the problems caused by the incumbents. As a result new start-ups are initially more likely to engage in sustainable entrepreneurship than market incumbents.

What sets sustainability start-ups apart from normal start-up companies is their pronounced value-based approach and their intention to effect social and environmental change in society. They are literally the Davids aiming to slay the giant. Realising that external costs cause environmental and social harm they make it their business to change market equilibria so as to internalize these costs and in the process to change the playing field for everybody. They do this by asking customers to pay a premium for socially and environmentally superior products.

However, the focus on their mission also has some drawbacks. Being involved with one specific innovation, sustainability start-ups have a tendency towards single issue campaigning. They invest all their resources and attention in optimizing one particular environmental or social issue at which they try to excel. So we will, for example, find that fair trade start-ups put price premiums at the top of their sustainability agenda; renewable energy producers prioritize the environmental impacts of energy production; and microfinance dedicated banks aim at providing loans to the poor. This might be due

to the fact that their entrepreneurs are simply obsessed with one issue. It is this obsession that has often driven them to launch the business in the first place. Given their limited resources, sustainability start-ups are, however, less good at addressing a broad range of sustainability issues. The fair trade labels, for example, have been hesitant to require their suppliers to embrace environmental issues (Equal Exchange, 2002; Robins & Roberts, 1997). Similarly there is little understanding among microfinance institutions, how their loans impact the environment (Lal & Israel, 2006). And some of the entrepreneurial firms in Germany's emerging solar energy industry have faced criticism about paying low wages, which could be seen as a lack of corporate social responsibility (Williamson, 2008). There are multiple reasons for this. On the one hand start-ups lack the resources to build up extensive sustainability management systems. Moreover, they are keen to keep communications focussed on their main innovation. Finally some sustainability entrepreneurs become caught up in their own propaganda. They eventually become convinced that their business is such a force for good that no dedicated management system is necessary.

While sustainability start-ups are keen to see their market grow, they are nonetheless often keeping that growth restricted. On the one hand there is a tendency among sustainability start-ups to keep standards undiluted and demanding. Being supported by idealistic stakeholders strongly committed to the sustainability mission, Davids are doubtful of any attempt to lower standards even if this might attract more customers (e.g. Lockie, 2008). Apart from idealistic reasons to keep the market niche committed to the highest environmental or social standards, there is also an economic rationale to this. Being aware that incumbents might easily outspend them in R&D and distribution,

should they decide to enter the market niche, sustainability start-ups might prefer to keep their niche at a size that is not attracting undue interest from incumbent competitors. Over time start-ups will try to continue innovating, thus pushing up requirements for sustainability performance. As a result sustainability start-ups have an inclination to keep their niches small and exclusive.

5.2 Greening Goliaths: The Transformation of Market Incumbents

In the early stages of an industry's sustainability transformation, market incumbents often react to pressure from stakeholders concerned about sustainability by adopting sustainability communication and management systems in an attempt to better understand the issues they are facing as well as to demonstrate to stakeholders that they are sincere about their concerns. However, incumbents are also restricted by their existing assets, which reflect past investments. These often anchor incumbents in a business as usual thinking, making it less likely that they engage in sustainability entrepreneurship. This is particularly the case when sustainability innovation might compete with extant products of the incumbent.

Market incumbents are initially challenged by newcomers where it concerns the primary innovation dimension of the sustainability start-up. Adapting all their product range to the highest sustainability standard is rarely an option. However, given their superior market power and investment capabilities, market incumbents can play catch-up quickly once they decide to become fast followers (e.g. Dimitri & Greene, 2006; Hockerts, 2006a). Incumbents may, for example, find it opportune to launch copy-cat products that

resemble those of the start-ups in order to reap part of the premiums that dedicated consumers are willing to pay. All major electricity utilities have, for example, launched some kind of tariff that promises their clients electricity from environmentally preferable sources (Bird et al. 2002; (Delmas, Russo, & Montes-Sancho, 2007). Incumbents may also decide to launch corporate venture capital (CVC) funds to keep an eye on innovating Davids (Teppo & Wüstenhagen, 2009). This provides them with an option to integrate sustainability innovation when it turns out to be disruptive.

While market incumbents tend to lag behind start-ups concerning the primary sustainability innovation, they do nonetheless have a tendency to invest in more encompassing sustainability management systems (Hamschmidt & Dyllick, 2001). Thus they will be addressing multiple environmental and social issues where sustainability start-ups focus on one or two issues only. Employing tools such as environmental and social management and reporting systems, market incumbents will find it easier to develop a broad sustainability performance.

Market incumbents are interested in less ambitious sustainability standards compared to sustainability start-ups. However, they are if anything even more interested in codifying these standards explicitly since they lack the reputation for environmental or social leadership that some sustainability start-ups have (Giovannucci & Ponte, 2005; Truffer, Markard, & Wüstenhagen, 2001). The existence of a broadly accepted product standard or label creates a level playing field allowing the incumbent to treat environmental and social performance as just one extra variable to be optimised. Incumbents will tend to attempt to keep standards fixed rather than encouraging continued innovation. The embrace of the Rainforest Alliance label by multinational Kraft can be seen as an

example for a multinational trying to enter the fair trade niche without having to subject to the stricter requirements (i.e. minimum price, price premiums, pre-financing, long-term contracts) of the Fair Trade Labelling Organisation (FLO) (McAllister, 2004).

5.3 *Interaction Between Davids and Goliaths*

Both Davids and Goliaths have a role to play in the sustainability transformation of an industry. In fact the interaction between the two can be likened to a seesaw whereby each side moves the transformation further. One can distinguish several phases of transformation (see Figure 2). In a first stage sustainability start-ups launch the sustainability innovation to the market. Often these start-ups are run by highly motivated idealists who work in close cooperation with NGOs and charities. Being placed in-between the third sector and the formal economy these alternative players do have profit motives although they are usually more driven by a desire to achieve environmental and social change. In his typology of ecopreneurs, linking the terms 'bio' and 'pioneer', Schaltegger (2002) calls these actors 'bioneers', while Zahra et al. (2009) refer to them as 'social bricoleurs' in the context of social entrepreneurship. Often these bioneers/bricoleurs never grow beyond a small niche thus actually not effecting disruptive change. However, in a few cases they can change into sustainable entrepreneurs. Both the organic food and the fair trade markets, for example, have seen many specialised producers (e.g. Demeter, CaféDirect) and retailers (e.g. One World Shops; Organic food shops) pop up in the early days of the movement (Dimitri & Greene, 2006; Hockerts, 2006a). Similarly, local grassroots initiatives engaged in producing their own solar collectors decades before the word cleantech became fashionable in Silicon Valley (Wüstenhagen 2000), and idealist bricoleurs preceded the

current quest for lighter, more efficient cars by a long time (Truffer & Dürrenberger, 1997).

While bioneers or social bricoleurs kick off sustainability transformation, they are usually followed quite quickly by some market incumbents once early growth picks up. These would usually be leading premium brands who offer line extensions to capitalise on the growing trend. Since the late 1990s, food producers and retailers have discovered the organic and fair trade niches for themselves (Villiger, 2000). Around the same time, incumbent electric utilities started experimenting with green electricity offerings (Bird et al. 2002), and car manufacturers have launched cleaner cars (Canzler & Knie 1995). Their offers usually make up only small line extensions. Retailers such as for example Sainsbury's and the Co-op have been early adopters of both organic and fair trade products.

As the sustainability transformation of a market continues, a different type of sustainability start-up company begins to emerge. The start-ups in this third phase are much more business-like and often backed by more professional investors. Having observed the development of the bioneers they have a good understanding of the market niche and now aim to extend it through more professional management. These start-up firms do not share the implicit motto of many bioneers that to stay 'small is beautiful' (Schumacher, 1974). Instead they have also a clearer expectation to achieve profitable growth and to extend market share and to defend it against incumbents. Examples for these types of start-ups include the organic retailer WholeFoods market in the U.S., the British Fair Trade Brand CaféDirect (Hockerts, 2006a), green power marketers such as

Green Mountain Energy in the US and Lichtblick in Germany (Wüstenhagen, 2000), and solar cell producers such as Q-Cells or Solarworld in Germany (Schönwandt, 2004).

The final and fourth stage of maturity of sustainability entrepreneurship tends to extend to the mass-market brands that begin to see both a growing risk from the start-ups and a market potential for themselves. Typical examples for this include WalMart's decision to enter the organic market (Gunther, 2006; Warner, 2006), Kraft's adoption of the Rainforest Alliance Label (McAllister, 2004) and the decision of energy incumbent Siemens to follow the lead of their competitor GE and enter the growing wind turbine manufacturing business in 2004 (Lewis & Wiser, 2007). Being more cost driven than premium incumbents, these late entrants into the sustainability niche often bring a logic of cost reduction along the supply chain to the table. WalMart, for example, explicitly aims to bring down the cost of organic food so that it no longer remains just a luxury item for the upper middle classes but also becomes accessible for typical WalMart clients (Gunther, 2006).

This trend of course increases the pressure to somewhat lower sustainability criteria and to give up some of the ideals cherished by the first generation pioneers (Lockie, 2008). The Fair Trade Labelling Organization (FLO), for example, has begun to relax some of its standards in response to the pressure from competing schemes such as the Rainforest Alliance label.

Figure 2: Interplay of Sustainability Start-ups and Market Incumbents in the Sustainability Transformation of an Industry

6 Conclusions

Sustainable entrepreneurship research so far has neglected the differential roles of large and small firms in transforming industries towards sustainable development. The theme has not been adequately addressed in the corporate sustainability literature either. While sustainable entrepreneurship scholars tend to focus predominantly on the role of start-ups, corporate sustainability scholars tend to focus their attention towards what happens in large firms. This article has aimed at advancing the academic discussion on sustainable entrepreneurship by (i) highlighting the differential roles of "Davids" and "Goliaths" in the sustainable transformation of industries, (ii) discussing the specific opportunities and challenges of "Emerging Davids" and "Greening Goliaths" as pathways towards sustainable development, and (iii) exploring the interaction of entrepreneurial initiatives in small and large companies in bringing about this development. Our analysis has resulted in a dynamic model of industry transformation, where the initial phase is characterized by sustainability initiatives of idealistic "Davids". In a second phase, some pioneering "Goliaths", for example retailers with a higher quality positioning, mimic some of the David initiatives and try to bring them into their mainstream distribution channels. In isolation, none of these two developments would necessarily lead to sustainable transformation of mainstream markets, because Davids tend to get stuck in their high-quality, low-market penetration niche, while Goliaths will sooner or later react to cost pressures by lowering the sustainability quality of their offerings. However, we see increasing evidence for a next stage of development on both paths. As for "Emerging

Dauids", firms such as Wholefoods, Green Mountain Energy, Vestas or Ben&Jerry's have found ways to scale up their sustainable innovations without unduly compromising on their sustainability ambitions. On the other hand, in the "Greening Goliaths" camp, there are examples of large firms such as Walmart, GE, Kraft or Toyota who have taken on the challenge of building sustainability into their mainstream business. Arguably, the success of emerging Davids, which can also be seen as a potential competitive threat, has been instrumental for some of these Goliaths to embark on the level of sustainable entrepreneurship that they did. Therefore, we would argue that the sustainable transformation of industries is not going to be brought about by either Davids or Goliaths alone, but instead that their interaction is essential.

Our conceptual model points to interesting avenues for further research. It has been suggested that social entrepreneurship research should move beyond the single case study designs in the early days of the discipline and towards larger samples (Hockerts, 2006b). This is certainly true for sustainable entrepreneurship research as well, but we would suggest that additional insights can be gained from comparative studies of sustainable entrepreneurial initiatives in both small and large firms. In such studies, it would be particularly interesting to watch out for the specific challenges encountered by "Davids" and "Goliaths" in their attempts to broaden and deepen the level of their impact. This could be done retrospectively by doing in-depth case studies on some of the cases of successful "Emerging Davids" and "Greening Goliaths" mentioned above. Even more insightful would be longitudinal case studies of a set of small and large companies moving towards sustainability, whereby the focus could be on either market or non-market strategies of Davids and Goliaths. There is also scope for empirically testing our

model in other industries such as the water sector or the greening of information technology services. A further area of interest would be to specifically investigate arenas where Davids and Goliaths interact. Looking at external corporate venturing programs in sustainability-related industries such as energy, water or transportation might be a good focus for that. Finally, further research could take an investor perspective and ask for the optimal portfolio allocation between Davids and Goliaths for simultaneously achieving high economic, social and environmental performance.

Our model also has important policy implications. The findings discussed in this paper suggest that what is needed could be referred to as an ambidextrous innovation policy for sustainability. O'Reilly and Tushman (2004) refer to ambidextrous organizations as those that master the art of simultaneously pursuing incremental and disruptive innovation. Similarly, achieving the sustainable transformation of an industry requires a finetuned mix of disruptive and incremental innovation, which can be promoted if policymakers understand the nuanced interplay of Emerging Davids and Greening Goliaths, rather than single-sidedly focus on one of these paths and neglect the other. Arguably, policymakers have a tendency to favour incumbents over entrepreneurial start-ups, so designing sustainability policies with an entrepreneurial perspective in mind is a good start, but smart ambidextrous policies would try to leverage cooperation and competition between Davids and Goliaths.
