Preface

We are extremely pleased to present the pre-conference proceedings of HWID2012. The conference is a working conference held under the auspices of IFIP TC 13 on Human-Computer Interaction.

1 Technical Committee TC13 on Human–Computer Interaction.

The committees under IFIP include the Technical Committee TC13 on Human – Computer Interaction within which the work of this volume has been conducted. TC 13 on Human-Computer Interaction has as its aim to encourage theoretical and empirical human science research to promote the design and evaluation of human-oriented ICT. Within TC 13 there are different Working Groups concerned with different aspects of Human-Computer Interaction.

The flagship event of TC13 is the bi-annual international conference called INTERACT at which both invited and contributed papers are presented. Contributed papers are rigorously refereed and the rejection rate is high. Publications arising from these TC13 events are published as conference proceedings such as the INTERACT proceedings or as collections of selected and edited papers from working conferences and workshops. See http://www.ifip.org/ for aims and scopes of TC13 and its associated Working Groups.

2 Working Group 13.6 on Human-Work Interaction Design

This working group was established in September 2005 as the sixth Working Group under the TC13 on Human - Computer Interaction. It focuses on Human-Work Interaction Design (HWID) and it is called WG13.6. A main objective of the Working Group is the analysis of and design for a variety of complex work and life contexts found in different business and application domains. For this purpose it is important to establish relationships between extensive empirical work-domain studies and HCI design. The scope of the Working Group is to provide the basis for an improved cross-disciplinary cooperation and mutual inspiration among researchers from the many disciplines that by nature are involved in a deep analysis of a work domain. Complexity is hence a key notion in the activities of this working group, but it is

© Springer-Verlag Berlin Heidelberg 2011
not a priori defined or limited to any particular domains. The aim of this Working Group on Human-Work Interaction Design (HWID) is to initiate new research initiatives and developments, as well as an increased awareness of HWID in existing and future HCI educations. See http://hwid.cbs.dk/
Cognitive Work Analysis: New Dimensions

Catherine Burns, PhD, PEng
Director, Centre for Bioengineering and Biotechnology
Director, Advanced Interface Design Lab
Professor, Systems Design Engineering, Univ of Waterloo
200 University Ave West Waterloo ON N2L 3G1

Cognitive work analysis (CWA) originated in the late 1970’s and 1980’s through the work of Jens Rasmussen, being collected and built into an effective methodology through the 1990’s work of Kim Vicente, and culminating in his book Cognitive Work Analysis (1999). Arising out of the challenges of trying to help people cope with the complex technical systems of nuclear power, CWA stood out as a method that acknowledged the complexity of systems and aimed to provide a formative rather than a descriptive approach to the design of support in these work environments. Furthermore, CWA offered a multi-faceted approach to understanding cognitive work, using several different types of models to build a rich picture. Since that time, CWA, and in particular its derivative design approach Ecological Interface Design (EID), has been widely applied in a vast range of complex, control-oriented systems. Since the 1990’s however, there has been an explosion of a new type of system – networked and distributed systems. These systems are characterized by their highly social dimension, resulting in new challenges in team problem-solving, community building, and trust allocation across distributed teams. Our recent work in CWA has focused on adapting CWA to face these new challenges and provide a solution that fits a truly social technical system. I will review our recent work in two areas: the development of specific team analyses to support CWA and the use of CWA for community building and social networking. Traditional CWA provides a solid base to move forward into these new dimensions. Overall, CWA should be treated as a living and adaptable approach to understanding cognitive work, grounded in a deep respect for the complexity of work environments and the expertise of the people who must work in them.
This workshop will concentrate on the extraction of design requirements from Cognitive Work Analysis. We will focus on the first three phases, work domain analysis, control task analysis, and strategy analysis. The fundamentals of the analyses will be explained in reference to past projects. The focus on the discussion will be how to use these analyses for design. Participants will have the opportunity to try out the approaches through guided exercises. Finally the workshop will conclude with a discussion of what other methods can be useful when incorporating CWA in interaction design.
Invited Talk

Applying Cognitive Systems Engineering to intelligence analysis

B.L. William Wong
Head, Interaction Design Centre,
Middlesex University
The Burroughs, Hendon
London NW4 4BT
United Kingdom
w.wong@mdx.ac.uk

In this talk, I will discuss how principles from Cognitive Systems Engineering might be used to design Visual Analytics systems to support intelligence analysts. In designing systems to control processes such as nuclear power generation, CSE has been used to determine and model a priori the functional relationships that relate the performance of the processes with system outcomes. Visual forms are then created to represent these invariant relationships in ecological interface designs. Can cognitive systems engineering be applied to the domain of intelligence analysis? And if yes, how might this be? And how should CSE principles be applied to the design of visual representations in intelligence analysis to take advantage of the benefits we have seen when CSE is applied to causal systems?

I will describe the intelligence analysis ‘process’ that is to be represented, the challenges it presents to representing the equivalent of functional relationships in intelligence analysis, and how the design of the visual forms can be guided by CSE principles such that they "... help users discover the unexpected—the surprising anomalies, changes, patterns, and relationships that are then examined and assessed to develop new insight" (Cook, et al, 2007).

Intelligence analysis is the process of transforming data into information that may be acted upon. For example, in criminal intelligence analysis, it is about identifying and providing “...insight into the relationship between crime data and other potentially relevant data...” (www.interpol.int). This is not merely reorganizing data and information into a new format (Krizan, 1999), but more importantly, to ‘connect the dots’ and to quickly find the few pieces of relevant information from very large datasets of mixed reliability, missing, and out of sequence data, and to piece them together in a way so that the conclusion makes sense and can be justified.

This is an intellectual process, rather than causal process governed by the laws of nature. Intelligence analysis sorts the “significant from the insignificant, assessing them severally and jointly, and arriving at a conclusion by the exercise of judgment: part induction, part deduction” (Millward, in Hinsley and Stripp, 1993), and part abduction (Moore, 2011, p3). Unfortunately, much of this process is presently very labour intensive and inefficient, and is becoming almost impossible as intelligence organisation face increasingly large data sets.

New software tools are being sought in order to facilitate the analysis of such large datasets. One approach to the design of such tools is known as visual analytics. This is the emerging “... science of analytical reasoning facilitated by visual interactive interfaces" (Thomas and Cook, 2004), “... combining automated analysis techniques with interactive visualisations ...” (Keim, et al 2011) that are specially designed to support the interactive dynamics (Heer and Shneiderman, 2012) to enable real-time analytic interaction with data. What is needed are methods and technology that facilitate the detection and assembly of related and relevant
information in a way that supports human sense-making and the communication of these assessments effectively for action (Keim, et al, 2011)

In intelligence analysis, and unlike nuclear power plants, the underlying information structures and relationships cannot be readily determined a priori to design. Meaningful interpretations of data to arrive at explanations or stories and narratives are instead constructed as the analysts read, analyse and learn about the data. Such information structures - the chains of evidence that are connected to tell a story - are formulated during the investigative process of intelligence analysis.

Just as we attempt to model the process as we design systems for controlling a nuclear power plant, we also need to model the intellectual processes involved in controlling the investigative and reasoning processes. I will therefore discuss visual thinking, sense-making and critical thinking in the investigative and reasoning analysis process. I will then draw on CSE and EID, and supporting literature in representation design, to address what is it that we ought to represent, and a number of human factors based principles of visual design, that we can use to deliberately guide our design of interactive visualisations. To close, I will give a few examples like how we use the concepts of "blackholes" to represent missing data, "brown worms" for deceptive data, and "keyholes" for peering at large data sets through a limited view port (Wong and Varga, 2012).

On the usage of different work analysis methods for collaborative review of large scale 3D CAD models

Pedro Campos and Hildegardo Noronha
Madeira Interactive Technologies Institute, University of Madeira
Campus Universitário da Penteada, 9000-390 Funchal, Portugal
pcampos@uma.pt, hildnoronha@gmail.com

Abstract. Human work interaction design is an emerging discipline that aims to encourage empirical studies and conceptualizations of the interaction among humans, their variegated social contexts and the technology they use both within and across these contexts. In this paper we describe and elaborate around the usage of different work analysis methods in a complex, real world work domain: collaborative review of large-scale 3D engineering models. The analysis is based on (i) input from experts in the oil platform engineering field, (ii) previous and related work and (iii) application of different methods considering the recent advances in technology. We conclude that hierarchical task analysis was not effective in obtaining a clear, common vision about the work domain. Storyboarding was the most useful technique as it allowed discovering novelty factors that differentiate the solution and improve the usability of the product, thereby supporting the human work at offshore engineering design and review sessions.

1 Introduction

Human work interaction design [1] is an emerging research field within HCI that is focused on the user’s experience of tasks (procedures) and the artifact environment (constraints in the work domain). That analysis and interpretation of human work is eventually manifested in the design of novel, technology-based products, systems and applications [1]. In this paper, we report on a seven-month research study around the requirements elicitation, scenario design and storyboarding processes for creating a new Virtual Reality (VR) distributed application to support a complex work domain: the collaborative review of large scale 3D engineering models, in the context of the oil and gas industry at a very large organization [2].

The current way of designing industrial plants relies on the communication among experts in several areas of the field, and on tools that allow the specification and simulation of the site. VR resources are used to visualize and interact with complex 3D environments in real time. Several engineering simulations employ VR to foresee the results of complex industrial operations.

In this paper, we analyze the user tasks at stake during collaborative sessions of 3D CAD models design and review in the specific context of the oil and gas industry. By studying the users’ work and needs, the related existing work and the possibilities that
recent advances in multimodal technologies, we expect to shed new light into how an integrated environment should be conceived and designed in order to positively influence the collaboration levels between dispersed teams of engineers that need to review oil platform problems and to design solutions for those problems.

Our main contribution to the Human Work Interaction Design (HWID) field is the comparison of the effectiveness of different work analysis and design methods towards establishing a common vision regarding a new product for the oil and gas industry engineering models’ review, in a collaborative manner. This is especially important for gaining new insight about the relative advantages between the different methods in a highly complex, real world work domain.

2 Background and Related Work

Human Work Interaction Design (HWID) is an emerging approach that promotes a better understanding of the relationship between work-domain based empirical studies and the iterative design of prototypes and new technologies [1]. HWID’s goal is to encourage empirical studies and conceptualizations of the interaction among humans, their variegated social contexts and the technology they use both within and across these contexts.

To achieve this, HWID promotes the use of knowledge, concepts, methods and techniques that enable user studies to procure a better apprehension of the complex interplay between individual, social and organizational contexts and thereby a better understanding of how and why people work in the ways they do. Therefore, one of the main characteristics of HWID as an interaction design approach is to focus the analysis on the how’s and why’s of people’s work. HWID also tries to promote a better understanding of the relationship between work-domain based empirical studies and iterative design of prototypes and new technologies [12]. HWID’s roots lie in Cognitive Work Analysis (CWA) [1, 6]. Cognitive Work Analysis (CWA) is a multidisciplinary framework for the analysis, design, and evaluation of human work developed by Rasmussen, and colleagues [7]. Its purpose is to guide the design of technology for use in the work place. CWA helps an analyst identify the activities and agents that are needed for a system to effectively fulfill its functional purpose. CWA can also be regarded as a formative process that focuses on an ever-increasing number of dynamic constraints that systems present nowadays, rather than prescriptive methods of working.

Storyboarding [4] is a common technique in HCI and design for demonstrating system interfaces and contexts of use. Despite its recognized benefits, novice designers still encounter challenges in the creation of storyboards. Many researchers have studied the benefits and disadvantages of storyboards, including Truong and colleagues [4], who presented two formative studies designed to uncover the important elements of storyboards.

Activity-based analysis [5], in particular activity theory methods, incorporates the notions of intentionality, history, mediation, motivation, understanding, culture and
community into design. In particular, it provides a framework in which the critical issue of context can be taken into account.

In hierarchical analysis [3], another work analysis method, the instructional designer breaks down a task from top to bottom, thereby, showing a hierarchical relationship amongst the tasks, and then the instruction is sequenced bottom up. Task analysis often results in a hierarchical representation of what steps it takes to perform a task for which there is a goal and for which there is some lowest-level “action” that is performed [3].

3 Usage of Different Work Analysis Methods

In the offshore engineering field, the project of deep-water production systems, including oil platforms, ships and all the subsea equipment that plays a part in the production process, is currently designed by means of complex computer modeling systems. The design of a new production unit is a lengthy and expensive process, which can last many years and consume hundreds of millions of dollars, depending on the complexity of the unit and the maturity of the technology required to make the project technically and economically feasible.

Offshore engineering projects involve not only geographically distributed teams but also teams of specialists in different areas using different software tools, both commercial and internally developed. While the interoperability of those tools is still an issue, it is a mandatory requirement for any collaborative solution.

One of the objectives we had was to establish a sound requirements document stating clearly the desired project’s objectives, requirements and specifications, as well as outlining scenarios for the solutions proposed and their evaluation procedures.

We used the resources available at Tecgraf-PUC Rio (the research arm of Brazil’s largest oil industry company, Petrobrás) [2] to conduct user observations and informal interviews with the engineers involved in collaborative engineering design and review activities. The final result we obtain is very important, since it allows us to understand: (i) the application domain, (ii) the problem of designing and reviewing CAD models, and (iii) the needs and constraints of the system’s stakeholders. Additionally, and perhaps most importantly, we elaborate on the relative advantages and disadvantages we faced when applying different work analysis methods: activity-based analysis [5], hierarchical analysis [3] and storyboarding as a way to understand the value of possible solutions [4].

3.1 Activity-based analysis

Activity 1: Designing and reviewing engineering models. Design review is the process of checking the correctness and consistency of an engineering project while making the necessary adjustments [2]. In the session, users can manipulate objects, highlight and create annotations, do measurements, check the proper ergonomic design. The ability to move, rotate and scale objects is important for various purposes, such as joining models, viewing hidden areas, planning the placement of new devices,
and simulating a maintenance or intervention operation in a process plant. Moreover, integration with an engineering database from the CAD system is useful to create annotations emphasizing critical parts (Figure 1). Comments attached to objects can also be used as recommendations for project management. Figure 1 shows a measurement taken for planning the movement of a large tank in a production unit. Users create annotations to guide the maintenance procedure and animate the entire operation. Finally, it is possible also to confirm if the space distribution of the engineering devices conforms to the ergonomic needs for operation and maintenance.

![Fig. 1. Annotating and measuring activities involved during design and review.](image1)

**Activity 2: Riser analysis workflow.** An important step in deep-water oil exploitation is the elevation of the oil from depths over one thousand meters to the surface. Oil platforms use ascending pipes, called risers, which are tubular structures that convey oil and/or gas from the wellhead on the sea floor to the platform’s separator system tanks [2]. To certificate the operation of the risers for their entire lifecycle (30
years or so), simulations of the stress applied to the riser system are conducted based on meteo-oceanographic data about wind, tide and water currents. Simulations are made under extreme environment conditions to test stress resistance. It is important to perform fatigue analysis studies to evaluate the most critical regions of the risers affected by cyclical stress in order to guarantee their integrity during their lifetime.

Conclusions after the activity analysis. The problem of providing engineering teams with effective tools for collaborative work is becoming increasingly important, not only because teams are increasingly working distributed throughout the world, but also because current tools still lack support for collaborative engineering design and review, either in co-located or distributed settings. The oil industry is especially well positioned as a potential demonstrator for research developments in this field, since it’s one of the largest user bases of high-end hardware and software.

Collaborative Virtual Environments (CVEs) place the emphasis on providing a common virtual space of interaction to distributed teams, a space where they can meet as if they were face to face, while sharing and manipulating the relevant work artifacts, in real time. In the case of this application domain, the oil industry, there is a relevant issue that motivates this project: the working force is aging, and the industry is not attracting younger generations of workers. Therefore, the trend of conceiving “digital oil fields” capable of being controlled remotely is becoming strategic for oil companies.

The essential scenario for solving this problem is a 3D interactive environment that represents the oil platform and associated subsea equipment, in a multi-touch virtual control room approach. The oil industry application domain, as referred in the previous section, fits well into the design and evaluation of novel environments, because of several factors. First of all, the very nature of the work performed by the engineers themselves, which is often carried out in collaborative, geographically apart settings. Secondly, because they can provide real world data in the form of large-scale CAD models, thus acting as reliable demonstrators of the project’s results. And finally, because there are - to our knowledge - very few research efforts specifically targeted at this application domain.

The final product the team performing this work analysis identified is essentially a large-scale virtual environment based on multi-touch and remote collaboration features for increased awareness and increased sense of presence among teams of oil industry engineers. The final prototype should consist of a set of computer clusters for multi-projection environments running the software designed, developed and evaluated throughout the project.

The main idea underlying this vision is that if we provide engineers with multi-touch collaborative tables and walls, we can achieve a state-of-the-art environment with an interesting application to the oil industry: a system that finally allows these users to find, navigate and visualize their complex CAD models’ data in a much more satisfying and effective way. This goal can be measured in two dimensions: the usability dimension, making use of well-know Human-Computer Interaction (HCI) evaluation methods and the collaborative dimension, using traditional measures for determining the levels of remote collaboration between geographically dispersed teams.
3.2 Hierarchical task analysis

In this work analysis, the hierarchical task breakdown was actually the first step the team took. The analysis was based on input from experts in the oil platform engineering field, several brainstorming sessions, semi-structured interviews and other meetings. The result (after many iterations) is shown in Figure 3. One of the positive aspects was the fact that the team was able to identify the most important tasks and the most intense tasks from a cognitive perspective. The downside was that the team remained without a clear picture about what should be designed and implemented, what was more important and what was less relevant. Other methods, as we will see in the next section, proved far more efficient in gaining a common vision.

Fig. 3. Task case map for our work domain analysis.

3.3 Storyboard-based analysis

Since the team had difficulties in synthesizing the work of offshore engineering design and review teams, we decided to employ storyboards [4] to facilitate the ideation process as well as to better explore the possible design concepts. Figure 4 illustrates a particular one (textual descriptions omitted for brevity).

Storyboarding was particularly beneficial to this project’s HCI design. It allowed matching the possibilities offered by recent advances in mobile, multitouch technologies with the cognitive tasks at stake.
After long discussions, the team chose to employ the power of tablets to create different navigation modes in a collaborative prototype where CAD models are simultaneously shared and visualized through Wi-Fi, while the user can also videoconference with other remotely located engineers. One of the navigation modes is depicted in Figure 4. The storyboard illustrates the use of sensors to control the camera’s orientation. Translations are performed through multi-touch gestures. The user is free to work whenever he wishes to, which is a significant step further regarding the current system being used by the company (based on traditional desktop-based PCs). Therefore, we can conclude that storyboarding was an effective technique to identify novelty factors that could enhance the usability of the proposed product.

3.4 Final Solution

The system is built upon the concepts of intuitive visualization and cooperation. To achieve our objectives while using those concepts we built several test navigation modes. Two of them ended up being selected for further improvement. Despite an apparent similarity on interaction styles, the two modes are quite different in both the technical and user interaction components: The first version uses built-in inertial sensors to position the virtual camera in a first person view manner, just as if the user was holding a real video camera and filming around. To allow the user to move around, it uses an in-screen touch-based joystick. The second version uses the tablet’s camera to track its position and orientation, relative to a tracker. It works as if the user was filming the object on top of a table allowing all the natural movements he would do.

The second version can’t use the built-in inertial sensors exclusively as none of them gives translation (the position can be doubly integrated from acceleration but the errors and drift are too significant to be useful). GPS, another possible alternative, can only work outdoors and doesn’t have enough accuracy for this problem. The solution is to use the camera to track an object and from that deduce the tablet’s position and
orientation. The camera tracking is a suitable solution as it provides a surprisingly accurate translation, rotation and, indirectly, zooming without the need of another artificial input (like the virtual joystick on the first-person view navigation mode). The first-person version can be shared between multiple tablets allowing one user to guide or show some feature on the model to the other users. Figure 5 illustrates this. The microphones and the front cameras are shared between multiple tablets, creating a videoconference that improves the cooperativeness of the system. A minor feature (freezing the camera) was also implemented. It allows users to freeze the current view and move around the tablet without fearing that the movements performed will change the camera’s position and without stressing body positions. This feature can be used when showing certain features on the models or even when working on the models themselves on future work.

Fig. 5. Two engineers engaged in a co-located collaborative design and review session.

4 Comparison between the different methods

Hierarchical task analysis was the first method employed in this product’s HCI design. Perhaps because of that it was the method that required more effort in order to produce a reasonable set of artifacts describing the engineers’ work.

Task analysis taken from a hierarchical perspective had its advantages. First, it allowed the entire team to understand the priorities in the design that should be taken into account. It also had the advantage of promoting discussion around a single diagram, which made it easier to reason about human work without losing the “big picture”. However, this method was the least efficient of all. The team remained without a completely clear picture about what should be designed and implemented, what was more important and what was less relevant.
Secondly, the method for trying out a more efficient work analysis was activity-based analysis. We tried to write a complete, detailed description of the collaborative engineering activities that are performed by offshore engineering teams, working both in the oil platform as well as in the central company’s offices.

The activity-based analysis effort was overall positive. By forcing a detailed description of the activities at stake, the team spent a lot of time and effort, but at least was able to reach a better work analysis. It allowed identifying a final, concrete product, essentially a large-scale virtual environment based on multi-touch and remote collaboration features for increased awareness and increased sense of presence among teams of oil industry engineers. The disadvantage we encountered was the fact that activity-based analysis did not allow the identification of novel ideas, and the brainstorming processes that usually lead to better UI designs was not well undertaken.

As mentioned before, storyboarding was the most useful technique as it allowed discovering novelty factors that differentiate the solution and improve the usability of the product, thereby supporting the human work at offshore engineering design and review sessions.

5 Conclusions

Supporting the needs of offshore engineering teams is an important industrial problem that should be addressed taking into account the rapid evolution in user interaction styles available. The potential for innovative solutions that is brought by tablet-based computing is enormous. In this paper, we described the industrial creation and evaluation experience of a new mobile system for collaboratively navigating and reviewing 3D engineering models, applied to the oil industry. We highlight that storyboards and scenarios were an effective way to elicit requirements together with oil industry experts, as opposed to high-level task analysis.

Our main contribution to the Human Work Interaction Design (HWID) field is the comparison of the effectiveness of different work analysis and design methods towards establishing a common vision regarding a new product for the oil and gas industry engineering models’ review, in a collaborative manner. This is especially important for gaining new insight about the relative advantages between the different methods in a highly complex, real world work domain.

Abstract. This paper describes an exploration of how children adapt their interactions with different graphical user interfaces (GUIs) in varied task situations. The effect of computer exposure, computer knowledge, attitude and motivation (computer-friendliness) on children’s (age 13-15 years) adaptations and performance was studied. No significant effect of computer-friendliness was found influencing their adaptations and task-performance. The participants were exposed to two different known graphical user interfaces (GUIs). The empirical data shows that participants performed equally well on both the GUIs by adapting their interactions. Also it was observed that a GUI which is rich in features facilitates user adaptations in coping with differences in task complexities. Thus between-task adaptations and adaptivity can emerge as a new usability measure for comparing alternate GUI designs, for users of all age group.

Keywords: Human-Computer-Interaction, User Adaptations, Graphical User Interfaces, Task Performance, Children

1 Introduction

Coping with different kinds of computing devices has become an essential skill for users of all ages including children. It has now become necessary for a child as young as 6 years of age to interact with various computing devices and interfaces especially in a learning environment.

As new computing and communication devices and software applications replace older ones a greater ability to adapt or discard them would be demanded of human skills. This study focuses on knowing what, when and how do children adapt to graphical user interfaces (GUIs). We have explored adaptations in interaction behaviour and task performances of children in changing situations.(Adaptation means modification in behaviour for improving performance due to change in environment.)

Empirical research work on user adaptations in interaction behaviour has been reported widely as seen in published literature some of which is reviewed below.
1.1 Related work.

Attempts have been made by researchers to capture factors affecting learner’s task performance and to find relationships among these factors. Personal goals, computer self efficacy,[1][2] motivation,[3] computer usage, anxiety,[4] age, [5] internet efficacy and attitude[6] have been reported to influence user interactions and satisfaction which may affect the success and failure of a task. A user with high computer self-efficacy or skills may also exhibit poor performance [2]. Inability to adapt to situations causes such perception-performance difference. A review of research on types, causes, effects and adapting ability of users is presented in following paragraphs.

Some researchers have tried to characterize or model these user-adaptations. Gray et al. [7] incorporated a new fuzzy based credit assignment scheme to model user’s adaptations in strategy selection. Freed et al. [8] proposed a new way of cognitive modelling i.e. modelling adaptations in one’s cognitive architectures in response to changing task characteristics or situations.

In coping with different task demands users adapt their strategies and levels in using software features. Heshan Sun [9] investigated the causes of “feature-use adaptations”. The observed causes were a new task, other person’s influence, change in working environment, discrepancy in system response and self deliberate initiative. Hayama et al.[10] found a new way to measure user’s adaptivity to software feature-use. They applied simple compression algorithm (LZW) to the user’s operation log to compute compression rate i.e. user’s adaptivity. Thus a new metric of measuring user’s interaction adaptivity was contributed. Schmitz et al. [11] used task-technology-fit theory to explain these adaptations. They segregated task adaptations(operational adaptations) from technology adaptations(software adaptations) and additionally found their strong relationship with perceived performance.

Smith et al. [12] found a novel mechanism of detecting drop in a search engine’s performance by monitoring change in user’s adaptations in querying instructions. They proposed that monitoring the querying behaviour of user can be used unobtrusively to indicate failure in system and adaptively upgrade the system.

In e-learning domain Merri et al. [13] investigated adaptations in selecting a learning-task using a shared-control (user+system) mechanism. In the experimental system a personalized learning-task list is first presented by the system and later user selects his learning-task from this list. The results showed benefit of this mechanism of user-adaptation and control in enhancing task involvement and motivation. Pieschl et al.[14] processed an e-learner’s interaction log and found that they adapt their learning process(time and interactions) to complexity of learning task. Between task adaptations were computed and summed to get a single score called “adaptation score” for each interaction variable. They concluded that adaptations in judged task complexity(JTC), number of accessed nodes (NAN) and use of hierarchical commands(HC) were significantly related in improving learner’s performance. We have used this adaptation score (ASI – refer section 2.1) as a measure to find magnitude of adaptations in search, modify and delete operations of users.
Grayson et al. [15] recorded eye-movement data to find whether unconventional interface design layout triggers an adaptation of visual search behaviour during repeated trials. Results of their experiment show influence of design characteristics like size, colour, boldness and location on adaptation of visual search behaviour.

The reviewed work shows no specific research related to adaptations in children using computers. Most of the findings were related to adaptations to task characteristics. Not much research has been reported about adaptations to system or interface characteristics or user’s personality. The authors of this paper have therefore chosen to research on adaptation phenomena in children.

2 Research Questions

This study therefore focuses on investigating adaptations in children to different graphical user interfaces through tasks. The aim was to establish relationship between adaptations and task performance. Children prefer drawing and gaming activities on computers the most. The authors have investigated children’s drawing skills on computers with different levels of task complexity and using different drawing tools(GUIs).

Terms relevant in this document are defined as follows by the authors.

i. Computer-friendliness = (Computer exposure)+(Computer knowledge)+(Motivation to use computer)+(Attitude towards computer)

ii. Adaptation Score \( (AS_X) \) of an operation \( X \) is

\[
AS_X = (|X_{T1}-X_{T2}|) + (|X_{T2}-X_{T3}|) + \ldots + (|X_{Tn-1}-X_{Tn}|) \quad \ldots \ldots \ldots [14]
\]

Where \( X_{Ti} \) = number of \( X \) operations during task \( T_i \) assuming tasks \( T_1, T_2, T_3 \ldots T_i \) are executed in sequence.

iii. Adaptivity is the ability of adapting as well as achieving an ideal performance level within minimum trials in response to change in surrounding environment.

We have investigated following research questions.

**RQ1** Does children’s computer-friendliness significantly affect their drawing performance?

**RQ2** Does task or interface complexity (tool used) significantly affect children’s drawing performance?

**RQ3** Does task or interface complexity (tool used) significantly affect children’s interaction behaviour or adaptations?
3 Method

3.1 Participants

Participants of this study were 40 students of two different English medium schools situated in Indian cities of Pune and Guwahati. The participants were familiar with Paint and PowerPoint software interfaces. The schools had computer education inbuilt in their curriculum. Details of participants are shown in Table 1.

Table 1. The participants

3.2 Material

Drawing Tools (Graphical User Interfaces - GUI). The drawing tools used were Paint (PNT) and PowerPoint (PPT). Paint was included because of its simplicity and familiarity. PowerPoint was included because of its popularity and ease-of-use. During informal group discussions with participants they were asked to give feedback on their perceptions about the two interfaces. These were counter checked with the task evaluator’s opinions. They are summarized qualitatively in Table 2.

Computer-friendliness preset questionnaires. Two questionnaires were designed for scaling computer-friendliness.

Questionnaire (Q1). – Consisted of 14 objective and 3 subjective items grouped into two scales capturing computer-exposure and computer-knowledge. Computer exposure was measured as usage in hours/week at home and at school. Computer knowledge was measured as knowledge of computer hardware, internet and applications.

Questionnaire (Q2). – Consisted of 15 objective and 1 subjective items grouped into two scales capturing computer-motivation and computer attitude. Motivation
was measured in terms of motivation for e-learning, computer affinity and possessiveness. Computer attitude was measured in form of beliefs and initiatives.

**Target Tasks.** Total four drawing tasks T1,T2,T3,T4 were administered to the child subjects as shown in Table 3.

**Task-Performance Evaluation.** To remove variability or bias in task evaluation, three evaluators evaluated the tasks of each participant. Average age of evaluators was 28 with experience of two years in design. Drawings were evaluated on the basis of how close the final outcome matches with the master-drawings D1 and D2 in all aspects. Each drawing task was evaluated using a 10 point scale. Average of evaluator’s scores was treated as task-performance score for that task.

### 3.3 Procedure

Twenty boys (20 numbers) and girls (20 numbers) from class 8 and 9 of two schools (Table 1) were chosen for the experiments. Participants were chosen randomly by the class-teacher. They were briefed about the study and asked to complete two questionnaires Q1 and Q2. After the questionnaire survey participants were given drawing tasks on computers. They were asked to complete four tasks as mentioned in Table 3 using appropriate drawing tools (refer Fig. 1.). Total time consumed for the entire experiment was around 1 hour. To judge drawing performance, drawing outputs were evaluated by expert evaluators having design expertise. (Refer *Task-Performance Evaluation* paragraph in previous section).
Semi-structured group interviews in two groups, were conducted to understand children’s mental model, beliefs and perceptions about GUI features.

All drawing tasks were recorded using CamStudio Version 2.00 (Copyright 2001-2003 by RenderSoft). The full-screen region was recorded with Microsoft Video-1 compression format, square yellow high-lighted cursor without audio recording.

4 Results And Discussions

Encoded questionnaire data was entered into statistical software (SPSS version-17) for analysis. Task performance scores were also computed and entered into SPSS.

The participants’ computer exposure, knowledge, motivation and attitude data was normalized to 10. The statistics of this data for the entire sample population is summarized in Fig. 2. and Table 4.

Results show that students have good knowledge of computers, high exposure to computers and possess positive attitudes towards computers. What lacks is motivation to learn. It is posited here that learning programs on computers need to be engaging and motivating for continuous learning.

4.1 Research questions

Does childrens’ computer-friendliness significantly affect their drawing-performance (RQ1)?

To answer this question correlation was done between computer-friendliness constructs and drawing performance scores of each task and average performance as well. Average task-performance (max=10) was computed as average of task-scores of T1, T2, T3 and T4. Computer friendliness (max=40) was computed as sum of scores of computer exposure, knowledge, motivation and attitude.

The results in Table 5 indicates that none of the factors contributing to computer-friendliness viz. computer exposure, knowledge, motivation and attitude influence the task-performance significantly. To a certain extent when seen in depth computer-friendliness partially influences complex task performance.

Figures from Table 5 indicates partial relationship between computer knowledge and motivation as well as between motivation and attitudes. Computer-friendliness has no direct influence on adaptations to GUIs. Therefore user’s adaptations to GUI may be connected with factors like interface design, task complexity, time constrain and interest in topic or motivation. This is investigated further in next section of this paper.

RQ1 : Computer-friendliness does not significantly affect the task-performance.
Does task or interface complexity (tool used) significantly affect children’s drawing performance (RQ2)? Dependant t-test (paired-samples t-test in SPSS) was conducted to see the effect of task-complexity on the drawing performance. For Paint with two independent tasks (simple, complex) the t statistics was \( t_{\text{paint}}(36) = 5.561, P < 0.0005 \) and for PowerPoint it was \( t_{\text{powerpoint}}(37) = 3.553, P < 0.001 \). This shows that user’s drawing performance is dependent on how complex is the drawing task. Which is evident in Fig. 3. Also the influence of task complexity on performance is more in Paint than in PowerPoint. This may be accounted to PowerPoint having more features to accommodate ease-of-change during complex tasks. An interesting hypothesis arises here: Do more features in a GUI lead to faster adaptation?

The mean task-performance in case of simple task for PPT=4.9297 and PNT=5.3338. Similarly mean task-performance in complex task situation for PPT=3.8676 and PNT=3.8429. This shows that task-performance is not influenced much by the GUI. A similar t-test was conducted to see the effect of interfaces on the drawing performances. For simple-task with two independent interfaces (Paint, PowerPoint) the t statistics was \( t_{\text{paint}}(36) = 1.321, P < 0.195 \) and for complex task it was \( t_{\text{complex}}(37) = .113, P < 0.911 \). This reassures that interface is not influencing the drawing performance to that extend. This is because in difficult task situations, users adapt their GUI interactions, and thereby achieve their goal successfully and efficiently. These user-adaptations can be at two levels (a)cognitive level and (b) interaction level. The second one is explored further in this paper.

RQ2 : The results of this experiment show that children once familiar with a particular GUI show differences in their performances only because of complexity of task executed and not the GUI. They adjust very well to the complexity of known GUIs in keeping performances same. Therefore when exposed to a new interface a child will
adapt and perform well (do less errors and take less time) after some trials or learning period. In this case what matters is how quickly he can adapt (adaptivity) to an interface. Are these adaptations or adaptivity dependant on interface characteristics or does it depend on individual abilities needs investigation.

Semi structured interviews of participants were conducted to investigate their perceptions and belief in this regards. These are depicted in the cause-effect diagram (Fig. 4).

Fig. 4. Cause-effect diagram for poor drawing performance

Does task or interface complexity (tool used) significantly affect childrens’ interaction behaviour or adaptations (RQ3)? To monitor interaction behaviour the search(S), modify(M) and delete(D) operations during each tasks (T1 .. T4) were computed by observing the Cam Studio video recordings of these tasks. It was observed that 95% of all operations were mainly search, modify and delete. Adaptation-Score(AS) [14] for each individual for each of these operations was computed as follows

\[
\begin{align*}
AS_{\text{search}} &= \left( |S_{T1} - S_{T2}| \right) + \left| S_{T2} - S_{T3} \right| + \left| S_{T3} - S_{T4} \right|
\end{align*}
\]

\[
\begin{align*}
AS_{\text{modify}} &= \left( |M_{T1} - M_{T2}| \right) + \left| M_{T2} - M_{T3} \right| + \left| M_{T3} - M_{T4} \right|
\end{align*}
\]

\[
\begin{align*}
AS_{\text{delete}} &= \left( |D_{T1} - D_{T2}| \right) + \left| D_{T2} - D_{T3} \right| + \left| D_{T3} - D_{T4} \right|
\end{align*}
\]

The statistics obtained for the entire group is shown in Table 6 and Fig. 5.

<table>

</tbody>
</table>
Fig. 5. Comparison of Adaptation Scores of interaction variables

Figure 5. shows high adaptation score for ‘modify’ operations compared to ‘delete’ and ‘searches’. It means that a child shows more adaptation in ‘modify’ behaviour while drawing. Therefore if a drawing tool gives a good support and flexibility of modifying drawing elements, it will prove to be a better interface when adapting to different situations. Similarly operations showing more between-task adaptations can be identified for e-learning interfaces as inputs to UI designers.

Figures of mean search, modify and delete operations in all tasks (T1..T4) were used to draw graphs (Fig. 6.) and analyse the trend in user adaptations across tasks and GUIs. The slope of graph reflects magnitude of between-task adaptations. Steep slope means large adaptations in behaviour to cope with new exposed task or interface.

Fig. 6. Adaptation behaviour across tasks
Figure 6 shows that magnitude of adaptations (slope of graph) for both (simple and complex) tasks is same. But when considering number of operations carried out (clicks), Paint is superior during simple tasks while PowerPoint is superior during complex tasks. In conclusion an intelligent interface that adjusts the appearance of its features by sensing task complexity would be more useful from user’s adaptation perspective.

User adaptation behaviour across GUIs (Fig. 7) shows that for feature-rich GUI (PowerPoint) adaptations are less than for the feature-poor GUI (Paint).

![Graph showing adaptation behaviour across GUIs](image)

**Fig. 7.** Adaptation behaviour across GUIs

The conclusion we can draw is that, in situation where complexity of task is high and changes frequently a feature-rich GUI proves beneficial from adaptation perspective. While in case where task complexity is low and stable user can adapt to an adaptable GUI and reconfigure UI features depending on task. This is visualized in Fig. 8.

![Graph showing task characteristics favourable for adaptations](image)

**Fig. 8.** Task characteristics favourable for adaptations
E-learning interfaces should fall in this second category where learning tasks vary slowly in their complexity levels influenced by the learner’s strategies and style.

RQ3: The answer to this question emerges that the adaptations shown in handling simple or complex tasks are same between interfaces. (Fig. 6). However between-task adaptations (from simple to complex) show significant difference among two GUIs i.e. Paint and PowerPoint. (Fig.7). Practical implication of this is that between-task adaptation can be used as a usability measure in evaluating usefulness of alternative interface designs.

5 Conclusions And Future Scope

This study shows that children’s drawing performance is neither influenced by their computer-friendliness nor by the GUI they use. Task characteristics affect the performance to a large extent.

Results also point to the fact that children show adaptations in their interactions to cope up with difficult task situations. Amount of features available in a GUI may influence these adaptations and adaptivity to changing task situations. A further study can be undertaken on this.

Lastly it was seen that a specific functionality or feature of an interface influences ease-of-adaptations like modify feature of a drawing tool. Interface designers therefore can make use of user’s adaptation patterns and limits, in building “adaptation-friendly interfaces”. A task-sensitive adaptive interface may be more useful in personalization and can support adaptivity in a better way.

This paper contributes to an idea of using between-task-adaptation score as a usability measure in evaluating usefulness of alternate interface designs. Can we also make use of user’s adaptation pattern as a tool for cognitive modelling is an interesting question that arises.

An investigation into interface characteristics influencing user-adaptivity is required. We need to study whether features available in interface or information architecture of interface or interaction design influences adaptivity. Cognitive adaptivity and interaction adaptivity can be two promising directions for future research.

Acknowledgements. The authors would like to acknowledge the help extended by the Principals of Jnana Prabodhini, Pune and Kendriya Vidyalaya IIT Guwahati. We are thankful to the additional support we got from computer teaching staff Ms. Rohini Dhavale, Mr. Rajeev Patel and Mr. Lukman Khan of these schools. tetsuro.chino@toshiba.co.jp

Abstract. We observed bathing assistance, night shift operations, and handover tasks at a private elderly care home for 8 days. We collected approximately 400 h of recorded speech, 42,000 transcribed utterances, data from an indoor location tracking system, and handwritten notes by human observers. We also analyzed speech interaction in the bathing assistance task. We found that (1) staff members are almost always speaking during tasks, (2) remote communication is rare, (3) about 75% of utterances are spoken to the residents, (4) the intended recipient of utterances is frequently switched, and (5) about 17% of utterances contain personal names. We also attempted clustering utterances into passages, and about 33% of passages contained only one person’s name. These results should be applicable in semi-automatic long-term care record taking.

Keywords: cooperative work, speech interaction, care

1 Introduction

Japan’s increasingly aging population is an important issue, one urgent aspect of which is caring for elderly persons with disabilities. Nowadays, care services are often provided by the devoted efforts of care staff at long-term care facilities. Care services are characterized by what we call “action-oriented intellectual services.” Care staff makes many decisions regarding medical care which require specialized knowledge. They also assist elderly persons with disabilities in many activities of daily living. Care service staff members have many types of professions and specialties. Also, care services must operate at all hours, throughout the year, and successfully doing so requires a high degree of information sharing among staff, for example, keeping records of care performed. [1] pointed out that medical staff spend much time on indirect care, including record keeping and information sharing. Conventional IT systems are fundamentally designed for desk work, however, and do not support the needs for hands-free and eyes-free operations suited to action-oriented intellectual services.

[2] and [3] proposed a “voice tweet system” to overcome these problems. In that system, “voice tweets” spoken by a staff member are tagged with the staff member’s
location and motion, spoken keywords, and associations with background knowledge, and based on these tags, the tweets are automatically delivered to an appropriate staff-
er. This system provides semi-hands-free and eyes-free communication among medi-
cal and care staff. Such a system requires knowing what kind of speech communica-
tion supports cooperative work in medical and care domains. We therefore performed
field studies at an elderly care home in Japan to analyze cooperative work and speech
interaction among care staff.

We report on a series of field studies and the insights extracted from analysis of the
collected data. The remainder of this paper is organized as follows. Section 2 de-
scribes previous works. Section 3 describes the field and the tasks examined. Section
4 describes the study methodology, and Section 5 presents an analysis of the collected
data. Finally, Section 6 gives our conclusions and proposed areas for future study.

2 Related Works

[4] analyzed dynamically formed teams in a hospital emergency room, and identi-
fied three key factors in the design of team communication technology: (1) maintain-
ing awareness within the team, (2) making informative interruptions, and (3) support-
ing role-based calling. However, this study was limited to a few directly connected
rooms on a single floor. Further investigation of more distributed locations, such as in
larger hospitals or care facilities with multiple stories, may therefore be necessary.

[5], [6], and [7] reported on the use of a commercial voice communication system
named “Vocera” in actual hospitals. They pointed out (1) that selecting communica-
tion artifacts is necessary, (2) that person-locating features can reduce human move-
ment, and (3) that remote voice communication has positive effects on the prioritiza-
tion and scheduling of tasks. They also described risks and problems associated with
voice communication devices.

[8] reported on an analysis of nurse-patient conversations in a Japanese hospital. They
found that most utterances effective for risk sharing are spoken by nurses who are
highly skilled at risk recognition and communication. In the “voice tweet system”
described above, sharing this kind of informative utterances as “voice tweets” can
have positive educational effects for the whole team.

3 Study Location

3.1 Care Facility

We performed field studies at a Japanese elderly care home over 8 days between
September 2011 and February 2012. Figure 1 shows an overview of the study loca-
tion. The building has four stories, with 40 private resident rooms, common living and
dining rooms, 1 care station, 1 bath area, and other rooms and spaces. Corridors, elev-
ators, and stairways connect the rooms.
3.2 Residents with Disabilities

About 30 residents were living in this building during our field study. For convenience, we classify residents into the following groups: Residents with slight disability are independently mobile with the aid of a device such as a cane or walker. Residents with moderate disability require a wheelchair and staff assistance to move around. Residents with severe disability are bedridden, and can only be moved by multiple staff using specially designed devices such as a stretcher.

3.3 Target Tasks

We observed and collected data on 3 tasks. The bathing assistance task involves bathing residents on the first floor of the building, and is performed by a special day shift team. The nighttime staff performs night shift tasks, which involve monitoring resident sleep, performing evening and morning care, checking vital signs on a schedule, responding to nurse and sensor calls, and attending to other needs as they arise. At scheduled shift changes, leaders of the incoming and outgoing shift personnel perform the handover task.

4 Methodology

4.1 Speech Data Collection

We collected over 142 h of “subject sounds” via microphones attached to staff members’ clothing. We furthermore collected another 142 h of “intercom sounds” via intercom lines, and more than 98 h of “environmental sounds” via microphones set up at various locations. We used IC recorders to record environmental sounds in
44.1 KHz 16-bit linear PCM stereo, and recorded subject sounds and intercom sounds in 44.1 KHz 16-bit linear PCM mono. Figure 2 shows the equipment used.

![Subject sounds](image1.png) ![Intercom sounds](image2.png) ![Environmental sounds](image3.png)

Fig. 2. Sound data collection equipment

4.2 Extraction and Transcription of Utterances

About half of the audio data was selected and automatically split into sound fragments. We set the threshold parameter for length of silence between fragments to 500 ms, and human transcribers flagged fragments that were human utterances. Finally, the human utterances were transcribed with time stamps and speaker identifiers. This resulted in more than 42,000 transcribed utterances.

4.3 Other Collected Data

We collected more than 64,000 staff location samples using a Bluetooth-based indoor location tracking system that we developed. Observers also videotaped subjects to get precise movement data with timestamps. Human observers traced staff movements onto paper, and investigated their actions. The observers recorded the time, place, participants, media, and a brief memo on the content of observed conversations involving staffers.

5 Work and Speech Interaction Analysis

5.1 Work Analysis of the Bathing Assistance Task

We chose the bathing assistance task for analyzing work and speech interactions, because this was the most complicated collaborative activity among our target tasks. The following is an overview of the bathing assistance task.

1. An “inner support” staff in the dressing room determines the next resident to be bathed according to a schedule. Staff performs the bathing task according to the disability level of the resident as follows:

   - For residents with slight disability, the inner-support staff calls the resident’s room via intercom and asks the resident to come to the bath area.
For residents with moderate disability, one or two “outer support” staff members go to the resident’s room, check vital signs, and then ask the resident to come to the bath area by wheelchair with their assistance. If the resident agrees, then the staff members assist the resident from the bed to the wheel chair, and bring the resident to the bath area on the first floor.

For residents with severe disability, two or three outer support staff members go to the resident’s room with a stretcher designed for bathing bedridden residents, and check vital signs. If the resident agrees and conditions are met, then the staff members assist the resident from the bed to the stretcher, and bring the resident to the bath area on the first floor.

2. After arriving at the bath area, the resident undresses with inner or outer staff assistance, according to need and availability.

3. Assisting staff also check the resident’s body and apply ointments or medicines if necessary.

4. The inner support staff helps the resident bathe in a specially designed barrier-free bathroom or a mechanized bathroom, as needed.

5. After bathing, mainly inner support staff helps the resident get dressed.

6. Outer support staff assists the resident from the first-floor dressing room to the second-floor common living and dining rooms.

7. In the living and dining room, other staff members provide support by drying the resident’s hair, bringing food, or helping the resident rest in the living room.

8. Finally, staff helps the resident return to his or her room.

Since multiple residents bathe at the same time, some procedures are performed simultaneously. Many factors can force changes in procedure. For example, residents may not be in their rooms, or their mental or physical condition may preclude bathing.

It is worth noting that the tasks of getting dressed and undressed provide residents with valuable opportunities to train and maintain their physical and intellectual abilities, so the staffers provide minimal support and focus on safety. The time needed for getting dressed and undressed differs from resident to resident and can reach 30 min in the longest case, but efficiency is not the primary consideration in providing high-quality services at elderly care facilities. Flexible collaboration is therefore necessary to ensure these tasks are performed smoothly.

5.2 Utterances Spoken during Bathing Assistance

We choose one bathing assistance task involving all female residents for our speech interaction analysis. The task was performed over one morning, and represents about 10% of the speech data described in section 4.1.
According to records provided by the elderly care home, 6 staff members had bathing assistance duties that morning. Among them, we focused on two outer support staff members, who we refer to as A and B. We selected them because they moved throughout the study location and interacted with many residents in many different situations at multiple times and places. Table 1 shows a summary of utterances by A and B and other staff and residents.

Table 1. Summary of the extracted utterances

<table>
<thead>
<tr>
<th>Speaker</th>

<td>-</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

From the data, 10,095 utterances were extracted. The outer support staff spoke relatively more than others, perhaps because of numerous stock phrases used with residents. The lengths of each utterance were similar for all speakers, perhaps due in part to the influence of our automatic splitting process.

Table 2 shows the spatial conditions of each conversation participant. Almost all utterances (99.4%) were face-to-face communications. The proportion of remote communication was only 1.0% for staffer A, and 0% for staffer B. Inner support staff calls slightly disabled residents in this task, so there is little opportunity for remote communication by outer-support staff. Introducing the voice tweet system at this location would have a significant effect, because currently outer support staff does not have access to remote communication media, which may force unnecessary movement.

5.3 Frequency and Intended Recipients of Utterances

We analyzed utterance frequency and the intended recipients of each utterance to know how often and to whom the care staff talks during this task. Figure 3 shows a time plot of utterances spoken by outer support staffer A (blue dots) and staffer B (green dots) during the 2.5 h of the bathing assistance task. Dots at the upper, middle,
and lower positions denote utterances spoken to residents, other staff, and oneself (monologues), respectively. Both A and B are almost always speaking during the task, and the intended recipients quickly change. In one instance, the collected data show an outer support staff’s simultaneous conversation with a resident and other staff in the dressing room.

**Fig. 3.** Time plot and intended recipients of utterances

Figure 4 shows the distribution of intended recipients for utterances by staffers A and B. For both, about 75% of utterances are spoken to residents, about 17% to other staff, and the remaining utterances are monologues. The frequency of utterances to residents may be evidence of the importance of direct face-to-face verbal communication between staff and long-term residents.

**Fig. 4.** Distribution of intended recipients of utterances of staffers A and B (outer support staff)
5.4 Names in Utterances

Accurate long-term care records are important for maintaining and improving the quality of care services. Meaningful long-term care records require several key types of information, such as who performed the care task, what kind of care was performed, for whom the care was performed, when the care was performed, and where it was performed. Mobile device–based support systems like the voice tweet system can automatically record data on who (staff), when (time), and where (location). But data about for whom care is performed (resident) may be difficult to acquire, because devices such as physical tags attached to residents may be considered dehumanizing. We therefore analyzed the appearance of personal names in the utterances spoken by outer support staffers A and B. Personal names appeared 703 times, 378 times for staffer A and 325 times for staffer B. Table 3 summarizes the distribution of personal names in each utterance. About 16.9% of utterances have at least one name that could be a clue as to who is providing care or to whom care is being provided. Such information could be used by an advanced voice tweet system to semi-automate long-term care record maintenance in future care staff support systems.

</tr>
</tbody>
</table>

5.5 Clustering Sequences of Utterances into Passages

To get more information about who provides care and for whom, from utterances for a semi-automatic long-term care record system, we attempted to cluster sequences of utterances into what we call “passages.” A threshold parameter of the time gap between sequential utterances allows merging series of utterances spoken by each staffer into passages. Figure 5 shows distributions of passages with specified numbers of names, for 13 different settings (from 0.1 to 60 s) of the threshold for the time gap between passages.
Given an appropriate parameter value (3 s in this case, at the orange vertical dotted arrow in Figure 5.), the percentage of passages with only one name can be dramatically improved from 16.1% (the unmerged utterances case in Table 3) to 32.6%, and the average time length of the passage will be 16.7 s. This rate is sufficiently high and this length is sufficiently short to be utilized for precise semi-automatic long-term care records in future care staff support systems.

5.6 Possible Extensions and Applications

Background knowledge on each person who works or lives in the facility (e.g. name, role, gender, shift/work schedule, profession, behavioral preference or tendency, etc.) can be utilized to disambiguate the referent of each referring expression (e.g., personal names or pronouns) appearing in each utterance or passage. Based on this information, together with automatically acquirable information (e.g., who, where, and when) from a mobile device-based platform, the future stuff support system can generate and suggest estimated candidates or outlines of long-term care records to the responsible staff member, and ask for confirmation. This mechanism may contribute to lower costs and reduced load of care staff for the indirect care, as well as to improved quality of long-term care records.

6 Conclusions and Future Work

We reported on a series of field studies at an elderly care facility. For eight days we observed three tasks: bathing assistance, night shift operations, and shift handover. We collected approximately 400 h of recorded speech, 42,000 transcriptions, data
from a location tracking system, and handwritten notes by human observers. We also analyzed speech interaction in a bathing assistance task. We found that (1) staff members are almost always speaking during the task, (2) remote communication is rare, (3) about 75% of staff utterances are spoken to residents, (4) utterance targets are frequently switched, and (5) about 17% of utterances contain at least one personal name. We also attempted clustering utterances into passages. The rate of passages with only one personal name can be raised to 33%. These results could be utilized in semi-automatic long-term care record taking.

Future targets for study include (1) an integrated analysis of not only the collected speech data, but also the location, action, and observed descriptions of staff actions, and (2) comparison with data from other hospitals to clarify differences and common aspects, helping to create general models applicable to the broader healthcare domain.

Acknowledgements

This project was joint research between the Toshiba Corporation, the Shimizu Corporation, and the Japan Advanced Institute of Science and Technology, and was supported by the Service Science, Solutions and Foundation Integrated Research Project Program of the Japan Science and Technology Agency under the Ministry of Education, Culture, Sports, Science and Technology, Japan.

Abstract. A usability model is a hierarchical structure between the key elements encompassing users, user interface and interaction between them. It is a generic template which is independent of usability evaluation methods and provides flexibility for adaptation in different contexts and domains. In this paper, a usability model for medical user interfaces, especially for ventilator systems in Intensive Care Unit (ICU), is proposed based on Norman’s action-based seven-step model to capture a related medical context. A ventilator system provides a respiratory support to critically-ill patients. Currently, a usability of user interfaces of ventilator systems is evaluated by typical usability evaluation methods from software industry. These evaluation methods miss out important elements in medical context. Therefore, a need for a specialized usability model for medical user interfaces is fulfilled with a proposed usability model encompassing vital elements such as medical user, user interface, ICU environment and time required. This usability model is validated first, through a human work analysis using videos of selected tasks with medical user interfaces and then, with an overview of critical factors affecting medical user interfaces in ICU. In future, a proposed usability model can be integrated with a suitable usability evaluation method for evaluating medical user interfaces to identify related medical usability problems more effectively.

Keywords: Usability Model, Medical User Interface, Human Work Analysis, Ventilator System, Intensive Care Unit, Usability Evaluation, Video Analysis.

1 Introduction

In Intensive Care Unit (ICU), there are several medical devices such as patient monitoring system, ventilator system, electrocardiogram (ECG) machine, syringe pump, arterial blood gas machine and defibrillator. Most of the medical devices have user interfaces along with related controls and buttons for interaction with medical users. Fig. 1 depicts a ventilator system with on-screen user interface. A ventilator system provides a respiratory support to critically-ill patients. Its user interface helps medical users to input and control multiple and diversified system parameters during patient care [18]. The user interface also displays vital information related with critically-ill patients. This information includes numeric values, icons, options,
menus, messages, graphs, tables or alerts [27] and is really important in communication with medical users.

There are various commonly observed usability problems with medical user interfaces in ICU such as poor legibility or contrast, right-handed design, lack of templates and intelligence, poorly distinguished alarms and alerts, no support in local language and poor feedback about device state and behavior [6, 25, 40]. Such problems may contribute to medical errors. Too many patients have been injured or killed because someone pressed a wrong button, misread a number, misplaced a component, skipped a step or overlooked a warning message [39] when using medical devices. In fact, medical error is a leading cause of death along with motor vehicle accidents, breast cancer and AIDS [42]. Many physicians, hospitals and even, manufacturers of medical devices may have to face medico-legal cases and liability claims.

Thus, usability of medical devices such as ventilator systems and their user interfaces, is evaluated using several usability evaluation methods such as heuristic evaluation, cognitive walk-through, rapid prototyping, field surveys, usability inspection, Goals, Operators, Methods and Selection rules (GOMS) model, usability testing, Keystroke-Level Model (KLM), think-aloud method, cluster analysis or severity ratings [2, 19, 20]. Most of these usability methods are typical evaluation methods from software industry and miss out important elements in medical context. Therefore, there is a need for a specialized usability model to bring such missed out medical context into usability evaluation of medical user interfaces in ICU.
In this paper, we have specifically considered touch-screen based ventilator systems. We have proposed a usability model for ventilator system, which encompasses the related medical context along with important elements affecting usability of medical user interfaces in ICU. This model can be used along with a suitable usability method for usability evaluation of medical user interfaces in ICU.

2 Related Work

There are several usability models proposed by researchers. These models are of different types and are discussed in this section.

Winter et al. have suggested two-dimensional quality meta-model of usability. It describes the user interface (input / output data and states) along with information about the situation of use (context and user knowledge) [41]. Abran et al. have provided a consolidated usability model with a baseline of ISO 9241-11 standard integrated with other relevant usability characteristics from ISO 9126 standard and other sources. These characteristics include effectiveness, efficiency, satisfaction, learnability and security [1]. Federici et al. have described integrated model of evaluation to measure the distance between the designer’s and the user’s mental models [12]. Ford has provided a detailed conceptual model of usability along with several classified variables. It has focused on three major types of contexts – user, task and environment, and each context is described in terms of classified variables. For example, user is identified with characteristics, knowledge and so on [14]. Clemmensen has proposed Human Work Interaction (HWID) model, which shows the characteristics of human work and the interaction during tasks and decision activities, individually or in collaboration. It also highlights impact of theory and environmental context on such interaction [10].

A comprehensive study of usability models as briefly summarized above, has led to identification of common characteristics of models.

</tbody>
</table>
The usability model provides -
- broad elemental breakup of the activity.
- hierarchical structure between the key elements.
- a generic template which is independent of usability evaluation methods.
- flexibility for adaptation in different contexts and domains.

Table 1 depicts a comparison table for usability models differentiating among six main models studied based on major aspects shown in first column of the table. Other columns represent usability models identified by names of authors proposing respective models. There are few observations realized during a comparison of usability models. The type of usability model is one from the related group - quality model, user-centered model, action-oriented model or work analysis model. Most of the models are non-iterative models expect Norman’s model. Most of them do not consider work environment or time requirement during the analysis. Few of them consider a restricted context in terms of task, situation or culture. None of the models consider medical context in usability analysis and evaluation.

Thus, though usability models are quite useful for usability analysis and evaluation, most of them are general-purpose and definitely miss out medical context. These models fail to identify usability problems and medical errors in ICU environment. Such failure may lead to patient injury or death [39]. Therefore, it puts forward an important research question:

**How to adapt the usability model in medical context?**

A user interaction with medical devices through user interfaces, is studied during usability evaluation. Such user interaction involves several tasks such as setting up a device, changing a device mode or parameters, updating patient record, monitoring patient’s condition through alarms and alerts or generating reports [39, 42]. A task-oriented work analysis involving medical users can provide a better insight about usability problems as well as medical errors. This aspect has directed a selection of Norman’s action-based model during research work. This model is iterative and therefore, it can help in improving prototype design during several iterations.

Norman has proposed a seven-stage action model, which is published in Psychological Review [28] and is represented in fig. 2, which was used initially to capture major action slips [29]. Norman’s model starts with goal formation. The aspect of execution contains stages for the formulation of intentions to act, the planning of a sequence of actions, and the execution of actions, while the aspect of evaluation consists of observation of the result, interpreting it and evaluating it to create new goals, if required. **Till-date, many researchers have utilized and adapted Norman’s action model with diversified perspectives in various domains such as Organizational Behavior, Telecommunication, Web Design, Public Interfaces, Computer Games, Aeronautics and Medicine** [3, 4, 13, 17, 23, 26, 31, 33, 36, 42].
Goldkuhl et al. have presented a general model of social action and have used it to characterize information systems as artifacts employed for organizational action [17]. This general model of social action is influenced by Norman’s model. As part of the project AVANTI (AdaptiVe and Adaptable iNteractions for multimedia Telecommunication application), the Norman Cognitive Walkthrough (NCW) method addresses the particular problem - the presence of design teams in different cities, even in different countries [31]. Babu et al. have used Norman’s action model to conduct online assessments that guides in understanding the complete interaction between a blind user and the Web in performing an online task [3]. Finke et al. have reported on a series of experiments carried out to determine quantitative and qualitative effects on user performance when interaction is split across large public and smaller private screens. The experimentation is designed based on Norman’s action model [13]. Kim et al. have introduced Eye Mouse and user’s Thinking (EMT) System that tracks eye and mouse, and records user’s thinking. For applying EMT system, EMT tool is developed to help a researcher to do usability test by recording the user’s experience and reproducing it visually. For defining perception, recognition, and behavior of users’ experience, Norman’s action model is used along with other two models [23]. Salovaara has presented appropriation understood as interpretation process in which user perceives in a tool a new opportunity for action, thus acquiring a new mental usage schema that complements the existing uses [33]. This model is close to Norman’s action model, but extended for learning during use. Barr has discussed implications of analyzing computer game actions using Norman’s action model [4]. Sherry et al. have discussed about how pilots form ‘mental models’ of the way system behaves and use these models to guide their interaction with the system based on Norman’s action model [36].
Norman’s action model has been also applied in medical domain. Zhang et al. have developed a preliminary action-based cognitive taxonomy of errors; both for slips and mistakes in the domain of medicine, based on Norman’s action model [42]. Malhotra et al. have proposed a cognitive workflow model in critical care environment. The representation of medical users draws inspiration from data processing systems and Norman’s action model, defining mental and system activities required for task completion [26].

Thus, Norman’s action model has been widely accepted model in several studies as well as domains. In design of usability model for medical user interface, Norman’s action model is selected as it is a sound conceptual action-based model. Also, it is possible to accommodate medical context in Norman’s model in terms of necessary elements (discussed in next section) in ICU environment. The proposed usability model for medical user interface of ventilator system is discussed in the next section.

3 Proposed Usability Model for User Interface of Ventilator System

A usability model for medical user interface of ventilator system is proposed based on Norman’s seven-stage action model as shown in fig. 3. In this usability model, all seven stages of actions highlighted in Norman’s model are considered along with certain alterations and additions as discussed ahead:

- A ‘medical user’ is added and a ‘physical system’ is replaced by ‘user interface’. These changes are required as the focus of proposed model is on usability, in which interaction among medical users and user interfaces of ventilator systems is dealt with. Thus, ‘medical user’ and ‘user interface’ are important elements in proposed usability model.
- Usability model starts and ends with ‘goal’ to complete the loop. The interaction with user interface of ventilator system is initiated by medical user, responded by user interface and evaluated again by the user for further action.
- A ‘response’ is added next to ‘user interface’ as a response is always generated in the form of display of or change in numerical values, messages, graphs, alerts and alarms with medical user interfaces [27]. Such response is a basis for activities ahead such as perception, interpretation and evaluation in usability model. The ‘user interface’ and ‘response’ are device-related items and therefore, grouped together as shown in fig. 3.
- Three important features observed with ‘user interface’ of ventilator systems are shown in the model – ‘Combination of physical and onscreen interface’, ‘High risk’ and ‘Long-distance visibility’ [5, 9, 21]. These features are shown connected with ‘user interface’ in the model.
- Along with elements - ‘medical user’ and ‘user interface’, other two vital elements - ‘ICU environment’ and ‘time required’ are also shown in the
center of the model. These elements should be considered in each iteration of usability analysis to capture a related medical context.

![Proposed usability model for medical user interface](image)

**Fig. 3.** Proposed usability model for medical user interface

The vital elements considered in usability model are discussed in this section in details.

### 3.1 Medical User

There are two major users of ventilator systems - physicians and nurses. They are primary users as they actually operate the devices during patient care in ICU [6]. Physicians and nurses differ from each other in mainly six aspects such as gender, language proficiency, education/training, eyesight, average work experience and numbers in ICU as shown in initial six rows of table 2. These comparative aspects are
identified based on field study and profiles collected of 12 medical users including 6 physicians and 6 nurses working in intensive care units. The numbers indicated in brackets in table 2 represent about positive entries for the related aspect. Remaining three aspects in table 2 depict roles and responsibilities of medical users identified in related literature survey [30, 34].

**Table 2.** Comparison between medical users – physicians and nurses

</tbody>
</table>

It can be observed that physicians and nurses differ significantly in their background and approach to patient care, which directly affects the manner in which they interact with medical devices in ICU. There is a noteworthy difference in a way in which they perform the task. For example, selection of ventilation mode may be executed by nurse, but it is generally on the advice of physician. This task is executed only by physicians in some intensive care units.

### 3.2 User Interface

The user interface considered in proposed model is for touch-screen based ventilator system. **Though ventilator system is mainly a therapeutic device, it also helps in monitoring of critically-ill patients** [11, 35]. It has a combination of onscreen and physical interface [18]. Physical interface includes a control panel with knobs, buttons, LEDs and/or indicator light. Being a therapeutic device in ICU, it is high-risk device. A long-distance visibility is involved in patient monitoring [9] with alarms and alerts of ventilator systems. These features are shown in fig. 4 and they should be considered in evaluation of user interfaces of ventilator systems.
3.3 ICU Environment

In ICU, several environmental factors affect user interaction with medical devices. These environmental factors include lighting condition, ICU layout, noise as well as interruptions and disruptions [9, 38]. There are three levels of lighting conditions in ICU. Low and average lighting conditions are observed at 0-100 lux and 101-500 lux respectively whereas extreme lighting condition is observed at higher range. These lighting conditions are derived based on light readings obtained from three ICUs selected at various times of the day. The consultation with physicians and the observations of ICU layouts has led to three commonly observed viewing distances, which can be applied in long-distance visibility testing. The first level is 6 feet (1.83 m), which is the length of the bed. The next level is 13 feet (3.96 m), which is quite common monitoring distance in smaller intensive care units [9]. The highest monitoring distance suggested is 20 feet (6.10m) which can be observed in some bigger intensive care units. The next environment factor is interruptions and disruptions, which include asking questions or for assistance, phone calls, exchange of information with others, presence of other patients [37] and movements of medical staff as well as devices. These environmental factors definitely affect user interaction with medical devices such as ventilator systems; especially during patient monitoring and can generate medical errors harming patient life. Therefore, such factors are included in proposed usability model for medical user interface.

3.4 Time required

In ICU, the time is a significant element during performance of tasks. The survival rates of patients are higher in hospitals and intensive care units where the emergency systems are efficient and quicker. In emergencies, physicians and nurses are required to provide a treatment to critically-ill patients in quick time. So, they interact with devices through user interfaces hurriedly during patient care. Such rapid and hasty execution of tasks during interaction increases the chances of medical errors as well as stoppages or delays creating a threat to patients’ life. For example, to set couple of ventilation parameters, it takes about 10 seconds with user interface of ventilator system; but this task may be delayed if nurse fails to understand that screen is locked or there is a delay in related physician’s advice. Therefore, a time required for a task is an important element in performance of task and is required to be considered in usability evaluation of user interface in medical devices such as ventilator systems.
4 Validation of Proposed Usability Model through Human Work Analysis

The proposed usability model for medical user interface of ventilator system needs to be validated. This validation is performed using two methods - video analysis and overview of critical factors in ICU, which are described in this section ahead.

4.1 Video Analysis

As this usability model is action-based model, one needs to capture and analyze action sequences of selected tasks. Therefore, video analysis method is selected for validation of model through work analysis. A video provides a remarkably rich and vivid reproduction of an event. It also provides a permanent record of an event and supports reviewing and analysis of data at later times. Kaufman et al. have presented an approach to usability evaluation of computer-based healthcare systems designed for patient use in their homes. This approach includes a video analysis consisting of verbal and non-verbal analysis along with micro-level coding [22]. Rogers et al. have analyzed a blood glucose meter for its usability using video analysis, in which transcription and coding is used [32]. During this research work, selected task performances are video-recorded in real-time ICU environment. Such recordings have captured interaction of users with medical devices as well as related display screens of devices in ICU environment. **The names of manufacturers, device models and user identities are not disclosed to maintain confidentiality.** Usability professionals also need to have basic domain knowledge about medical users and devices such as ventilator systems for applying the proposed usability model. This section includes necessary steps involved in video analysis.

4.1.1 Selection of Representative Users

There are two major types of users of ventilator systems - physicians and nurses in ICU. They are primary users and actually operate the ventilator systems during patient care. These users differ on range of aspects such as gender, language proficiency, education/training, eyesight, average work experience and numbers in ICU [30, 34] as seen in table 2. It is not possible to employ a fully representative sample and therefore, a convenient sampling method is used [24]. Two ventilator systems are studied and related videos are captured. Nurse is involved with videos of first ventilator system and physician is involved with videos of other ventilator system.

4.1.2 Selection of Representative Tasks

In patient care, several tasks are performed by physicians and nurses with ventilator systems in ICU. The list of tasks includes setting a system, pretesting of a system, setting a mode, changing parameter values, setting up alarms and alerts, patient monitoring, updating patient record and generating a diagnostic report [11, 35,
It is observed that two tasks - setting up a ventilator system and changing parameter values are most frequently employed tasks by medical users with ventilator systems. During these tasks, medical users extensively interact with ventilator systems through user interface. Such interactions often involve device displays, touch screen interaction or use of controls/knobs and may have effect of surrounding ICU environment. Therefore, these two tasks are selected for video-recording and related two videos are recorded for each ventilator system.

4.1.3 Conducting a Video-Recording

Setting ventilator systems and make them operational typically takes about 5-10 minutes if no other interruptions or distractions happen in ICU environment. Such setup is tested before video-recording the user interaction. It is very hectic and tricky challenge to get an access to busy intensive care units [8] and to obtain permission for video recording there. A problematic spatial layouts and noise in the surrounding also create hurdles for video-recording process. The primary focus of video-recording has been on tasks performed by medical users through user interaction with ventilator systems. Important activities such as hand movements of users, data presented, selection of options, responses displayed and delayed device responses are captured in video-recording. The camera model used for video-recording is Pentax Optio M20 with resolution of 7 Megapixels. The file format of the recorded video file is .mov and the software used for video-logging is VLC Media Player 1.1.5. The video-recording is conducted in late afternoon with an average lighting condition.

4.1.4 Preparation of Observation Table

For each video recorded, an observation table is prepared. A part of observation table related with a video of physician setting up a ventilator system is depicted in fig. 5. There is an attempt to realistically record the observations about interaction between medical users and ventilator system while performing the tasks. Few of the field observations and activities in surrounding environment during recording session are noted. The observation table shows a chronological sequence of activities involved in a particular task. The details of each activity are mapped onto various stages and vital elements of proposed usability model. During the mapping, the stages and elements are divided into five groups. This grouping can be noted in columns represented in the observation table of fig. 5. The grouping is mostly sequential as per the stages of the usability model. In the first column of mapping, medical user, goal and intention are grouped together as such details are necessary in a preparation before execution of task. The related entry in fig. 5 is - ‘Physician is right-handed. Physician is setting a ventilator system’. The next column has two stages - Action specification (A) and Execution (E) as these are closely associated with execution of task. One such action is unlocking the screen. The next column has a group of entities related with user interface and related response. For example, on-screen user interface shows six options for selection of ventilation mode and selected mode is highlighted on the screen as a response.

</table>

Fig. 5. Part of observation table related with a video involving physician setting up a ventilator system.
The factors related with ICU environment and time required, are highlighted in fourth column. The LEDs for power source can be observed from a distance (max. 6 feet) during patient monitoring and therefore, are not suitable for long-distance visibility of alerts. Time required for an activity during user interaction is facilitated by a response provided through a user interface. At times, a physician needs to wait for few seconds to get the required response. The last column has a group containing stages - perception, interpretation and evaluation as these stages are related with evaluation of response provided by user interface. At times, an inquiry or a confirmation of details in this column is required and it is achieved through interview of user. Physician has confirmed the confusion about how many options to be selected for patient configuration. The options displayed in capital letters for patient configuration are difficult to read. Also, icons are not used for providing these options though well-accepted icons for ‘Paediatric’ and ‘Adult’ [7] are easily available.

Thus, observation tables have several important observations about user interactions with ventilator system. These observations are analyzed to capture related medical context as discussed in next section.

4.1.5 Data Analysis

The details of activities segregated into five groups in observation table are studied and analyzed. Many observations in the table highlight some important usability problems associated with vital elements. The findings in data analysis are discussed in this section.

Medical User: In data analysis, many aspects of medical users are revealed. Though nurse is right-handed, she has to operate the user interface using left hand due to space constraint. Nurse uses a middle finger; instead of index finger to operate touch screen as shown in fig. 6. But, other fingers are more error-prone than index finger during touch screen interaction [16]. Nurse has also fumbled during selection of ventilation parameters as she failed to understand that screen is locked.

User Interface: In data analysis, many usability problems are identified in user interface of ventilator system. The arrangement of multiple options in menu can be improved. The three options in the dialogue box for ‘Patient Select’ are quite distant from each other and six options arranged in dialogue box - ‘Screen select’ are asymmetric as depicted in fig. 6.

Fig. 6. Inappropriate grouping and symmetry of options in menu
Ventilator system is a therapeutic device with important high-risk therapeutic tasks such as a selection of ventilator mode and setting up ventilation parameters. A confirmation of such tasks or actions is desirable, which is not provided in user interface of one of the ventilator systems studied.

**ICU Environment:** There are several factors related ICU environment, which are highlighted in observation tables. The light reflections are noticed on and around the device screen and they obstruct the visibility of data on the screen. This is highlighted in the observation – ‘Glossy screen reflects face of the nurse’.

Fig. 7. Layout of ICU depicting dimensions and positions

Another factor highlighted in observations is ICU layout, which affects the viewing distance in ICU [9]. One of such ICU layouts, where this study is conducted, is provided in fig. 7. This layout is developed to understand the room dimensions and positions of doors, monitoring stations, beds as well as medical devices. In ICU layout, B stands for Bed position; D stands for Device position; M stands for Monitoring station. The lines between monitoring stations (M) and devices (D) show the viewing distances in feet. The horizontal and vertical arrows depict the spatial dimensions of ICU in feet. A monitoring station is a place in ICU from where nurses or physicians monitor conditions of critically-ill patients. It is at minimum of 13 feet (3.96m) from devices as seen in fig. 7. From the observation table shown in fig. 5, it is clear that the LEDs indicating power source or alarm in ventilator system can be observed from a short distance of 6 feet (1.83m) only and are not suitable for a long-distance visibility (upto 20 feet/ 6.10m). Another environmental factor highlighted in observations is interruptions and disruptions. Discussion among medical staff in a surrounding contributes to noise in the ICU environment as indicated in fig. 5. Multiple and undesirable alarms also generate noise.

**Time required:** In time-critical environment like ICU, most of the tasks are performed hurriedly in minimum time. Physicians and nurses are quite often busy in patient care and dealing with emergency. A nurse or physician needs to wait as ventilator system takes time to start-up or boot-up. It makes the user little impatient.
4.1.6 Result

A data analysis of videos recorded shows that the proposed usability model is able to capture more aspects of medical context in ICU environment. Such aspects or observations include light reflections, noise, arrangements of options, use of other fingers with touch screens, therapeutic actions, long-distance visibility and delays in device responses. Thus, a proposed usability model is validated through human work analysis using videos and it definitely captures required medical context in ICU.

4.2 Overview of Critical Factors in ICU

A comprehensive overview of critical factors is taken with a literature survey of relevant research publications about ICU. The critical factors, which affect user interface design of medical devices such as ventilator systems, are identified. These critical factors are categorized with a due consideration to vital elements of proposed usability model such as medical user, user interface, ICU environment and time required. This categorization of critical factors is depicted table 3.

The categorization of critical factors is discussed in this section. Few critical factors are related with medical users and may affect user interaction with medical devices. There are various types of physicians such as specialists, ICU physicians, resident physicians and interns with varying levels of critical care training. The ‘skills of nurses’ is a critical factor, which affects a patient care in ICU. These skills include safe medication, patient monitoring, respiratory or orthopedic care, record keeping, assistance to physicians and patient or family counseling [30]. Familiarity of equipment, procedure or environment of the medical user can affect one’s task performance. Such user skills or features as highlighted by critical factors should be considered in design, analysis as well as evaluation of medical user interfaces.
Several critical factors affect the user interfaces of medical devices. Ventilator systems provide a respiratory support to critically-ill patients. A manner of usage or therapy applied is required to be considered in interface design of ventilator systems. A complex work and information flow provides a challenge for interface designers to incorporate it into effective user interface. Alert and alarm design demands a special attention as they are needed in patient monitoring in ICU. A correctness of default thresholds in parameter values is required for efficient patient care in ICU.

Environmental factors in ICU are also important. A major factor is interruptions and disruptions, which include questions asked for assistance, phone calls, exchange of information among medical staff [37], presence of other patients, noise from medical devices and surrounding people. Other environmental factors include lighting condition and ICU layout [38], which also affect the long-distance visibility of user interfaces in ICU.

Emergency with critically-ill patients puts a constraint on the time provided for performing a task by medical users. The tasks such as setting up a ventilator system providing respiratory support to patient need to be executed immediately. An ‘urgent high-risk decision-making’ is a factor affected by processes like cognitive tunneling, which is a tendency of physician to focus on only one hypothesis or solution at a time and ignoring other possibilities [15]. Such decisions affect the time required for a therapy provided by medical devices such as ventilator systems.

These critical factors in ICU affecting user interface can be categorized as per vital elements related with proposed usability model for medical user interface of ventilator system as observed in table 3. The consideration of vital elements in a proposed usability model can direct usability professionals to many of these critical factors affecting user interfaces of ventilator systems and can help in capturing a required medical context in ICU.

5 Conclusion & Future Work

Usability model for user interface of ventilator system is proposed based on Norman’s seven-stage action model. This comprehensive model brings related medical context into human work analysis in terms of vital medical elements such as medical user, user interface, ICU environment and time required. It captures usability aspects like light reflections, noise, arrangements of options, use of fingers with touch screens, therapeutic actions, long-distance visibility and delays in device responses. This model can be used as a template with medical user interfaces effectively by usability professionals for improved results. In future, a proposed usability model for ventilator system can be integrated with a suitable usability evaluation method to identify related usability problems with medical user interfaces more effectively.
Acknowledgements

We appreciate a cooperation extended by physicians - Dr. Ajit Adangale, Dr. Harshwardhan Anturkar and Dr. Rajiv Doshi along with the nursing staff during the field work and video-recording in ICU. We are grateful to other RPC members - Prof. Uday Athavankar, Prof. Ravi Poovaiah and Prof. Azizuddin Khan for their useful suggestions during APS presentations. We thank Ahmed Hamja for his support to research work through photography in ICU. At last, we thank Uday Sagale and Dhiraj Jadhav for their assistive support in documentation and related editing during the research.

Abstract. A questionnaire survey is a necessary method of data analysis for investigation and research, but often it has a discouraging effect on the respondents because of the impression of being time-consuming and boring. In this paper, we describe the use of an interactive online questionnaire to facilitate a photovoltaic (PV) application research project led by the University of Southern Denmark. The questionnaire is developed by means of participatory design that has helped us get a balanced perspective between user needs, market viability, and technical feasibility. It makes participants better understand a specific technical knowledge that improves the research result.

Keywords: Participatory design, Solar energy, Game-like questionnaire

1 Introduction

Today, a well-designed solar system will generate considerable power at a competitive price. A photovoltaic (PV) system consists of several high technological components that should be compatible with each other, adaptive to the installation environment, and accordant to specific user’s need. We have needs to build an interactive tool for communicating effectively with target user. The development of this tool and subsequent usability research is part of the Sunrise-PV project.

The Sunrise-PV project is an industry-oriented project led by the Mads Clausen Institute (MCI) at the University of Southern Denmark and with the participation of Danfoss Solar Inverters A/S (DSI), Sydenergi (SE), Linak A/S, Esbensen Rådg. Ing. A/S and ProjectZero A/S. The project is partly funded of the Danish “Region Syddanmarks Vækstforum” and the European Regional Development Fund. Two large solar plants are party financed by the project, a 28 kW PV-plant on EU CSyd and a coming 80 kW plant at Produktionshøjskolen, both in Sønderborg, Denmark.

2 The research

2.1 Research issues

Basically, it is known that PV systems have advantages regarding environmental acceptance, as they, unlike wind energy, do not produce shadow effects from wings
nor acoustic noise. Furthermore, they only have little visual impact on the landscape. Thus, they are fairly easy to integrate into a specific site. However the public does not commonly know these advantages. The general focus on utilizing PV-energy is orientated on practical factors such as price, payback time, and installation requirements. To take PV energy into mass markets, we need to facilitate from two sides. One is to hear the perspectives of end users, technicians, government, and scientists. The other is to popularize the knowledge and current state of PV systems.

The initial focus was aimed at residential buildings. To get practical experience from private house owners and professional knowledge from stakeholders, a questionnaire survey was selected as method for the investigation. However, respondents often consider a questionnaire survey time-consuming and boring, which has a discouraging effect and lowers the quality of the end result. Therefore, we decided to develop a web-based program in the form of a game-like questionnaire to make the respondents enjoy the process of participating. The main questions for developing this program were how to choose the content and how to design the game-like interactions. The participatory design process provided rich materials to solve these two issues.

2.2 Approach for participatory design

The content of the interactive questionnaire is selected from the range of previous solar energy research that was focused on five basic fields. Much discussion has been on the balance between some of the following aspects: Economy, Ecology, Art, Technology, and Usability [1][4]. Solar energy has no significant predominance over wind power or waterpower in terms of economy, ecology, and technology. Governments or large companies always plan the construction of wind or waterpower. However, to mass market, the owner of a private house is more concerned about art and usability. Thus, we put the focus of the questionnaire on Art and Usability.

The process of our research was mainly separated into three steps: The investigation of the current situation and existing applications, the communication with local companies and private homeowners in four important towns, and the implementation of the interactive questionnaire. The outcome of each step contributed to the next step as design material.

Our participants were classified into four groups: end users, demonstration sites owners, technical support, and research specialists. Each group plays different roles in each step of the process. E.g. the end user group played a complimentary role during the investigation step, since the first step is put focus on studying and collecting fundamental knowledge about existing state of affairs of PV solar energy. But in the second step, the user is the core group to which we introduce the knowledge and send questionnaires to. The user’s active feedback is the significant to the research result. They list out the priority between each research field, and speak out their own experience and story about solar and green energy.

The cooperation of the organizations and companies synthesized architectural design, user research, marketing investigation, and solar system testing. We have paid particular attention to the knowledge and experience of technology development, sun tracking, green energy innovation, and building installation. The basic introductions and choice questions of each field are integrated in the interactive questionnaire.
3 Investigation, Communication, Implementation

After the investigation of synthesizing data from Internet search, public research reports, and library resource, we build communication with experienced owners of solar plants. Danish town Skive have been placed several solar energy facilities on public buildings. All schools and many institutions currently receive energy from solar panels in Skive. According to the calculations, one of the projects, which were set up in 2009, is expected to have a payback time of approximately 12 year [2]. The experiences from Skive showed us an exemplification of utilizing solar system in the Danish geographical condition that it has relatively less sunshine in the world, and that daylight is much longer in summer. The top three remarkable aspects of Skive government are capacity, cost, and size, for which we particularly created one section in the interactive questionnaire to see other participants’ perspective.

Our investigation also involved local policy. The Danish government has special law that allows a household photovoltaic installation that is smaller than 6 kilowatts to use net metering. The configuration of a 6.4 kWp PV system needs 41 square meters, and costs in the order of 126,000 DKK in 2012[3]. Building Integration Photovoltaic (BIPV) is one of the relevant fields of our research. BIPV is a solution that not only generates energy but also protects facades with nice design [1]. As architects have right to design and choose materials, we contacted architects who are members of our network in Denmark. They indicated their interests are in environment matching, light orientation, and energy generation by priority. They also preferred to use pictures to show their ideas, which inspired us to insert BIPV pictures in our program. See Fig 1.

![Fig. 1. BIPV example in the game-like questionnaire](http://bit.ly/U1Q2YQ)

We designed several posters which published on our website (http://bit.ly/U1Q2YQ) to share the aforementioned investigation to other participants, especially to the end user group, who had outdated information of solar system. To get an overview of users’ feedback in Southern Denmark, we held four seminars and took turns in Odense, Sønderborg, Esbjerg, and Kolding. SydEnegi, Danfoss Solar Invertor (DSI), ProjectZero, and Mads Clausen Institute gave a presentation to household owners in their professional perspective, respectively. During these seminars, we took chance to interview participants about their perspective of solar system, invited them visit our website and try the interactive game (questionnaire), and leave emails to keep future tracking survey. We use the words “game” instead of “questionnaire” to attract people come and participate the research actively.

Based on the investigation in market and communication with end user group, we mapped the interest and focus of core developers, external cooperators, and end users in terms of what advantage PV can bring to our life, how to choose PV types, and how to use PV to help architectural design. The map shows the priority of the interest
by the size of text as Fig 2. Consequently, these keywords showed us the most important concerns are payback time, why purchase a solar system (purpose), and appearance. We designed another section in the program that allowed participants to choose their preference in these three aspects.

Fig. 2 Keywords of participants' interest

Fig. 3. A game-like questionnaire

The program combined information, introduction and collection and gave us several different approaches (Fig 2) for interacting with the participants. We called it 'game-like', because the whole process includes a variety of sections and tasks. Since questionnaires are generally considered boring, time consuming and long, we decided to design the questionnaire as a game in order to attract participants and keep them interested in accepting and providing information. It includes multiple choice questions, sorting order questions, and open discussion tasks. The test of the online program can be found on http://bitly.com/S38Jvq (See Fig 3). The input from the respondents is stored in a database. So far, we collected more than 40 answers that include all different kinds of respondents and show a balanced interest of design concepts. The top choice of the scale of a solar system is in 40-80 square meters in size, the price is between 70,000 and 120,000 DKK, and expected payback time is less than 10 years. Seventy per cent of the respondents pay attention to the appearance of the solar system and most of them looked forward to a feature of knowing operational details of the solar system.

A web based game-like questionnaire is aiming to provide an enjoyable and relaxing experience through participatory design. It clears up and re-organizes the mass of information from abundant research to help respondents better understand professional information. It does not only provide constructive suggestions but also addresses practical issues. This balance between negative and positive feedback will generate a new understanding and thus lead to new research and future development.

A Design Science Approach to Interactive Greenhouse Climate Control using Lego Mindstorms for Sensor-Intensive Prototyping

Rasmus Ulslev Pedersen, Dept. of IT Management, Copenhagen Business School, Howitzvej 60, 2000 Frederiksberg, Denmark, rup.itm@cbs.dk

Torkil Clemmensen, Dept. of IT Management, Copenhagen Business School, Howitzvej 60, 2000 Frederiksberg, Denmark, tc.itm@cbs.dk

Abstract.
In this paper we present a case study of early prototyping work performed within a Danish advanced technology project. We specifically investigate the problems and issues related to throw-away prototypes in sensor-intensive systems. An important criterion is to record and perhaps later reproduce the identified contributions of the throw-away prototypes, and to this end we use the educational version of Lego Mindstorms NXT. To achieve methodological rigor we have used the Design Science Framework by Hevner et. al. It allows us to focus on the prototyping effort (called the design cycle) without letting go of either the relevance or rigor related to the project. We relate the case study to a Human Work Interaction Design (HWID) framework for the use of interactive, sensor-intensive prototypes to develop interactive greenhouse climate management systems. By applying guidelines suggested in design science to the case studied, we identify a number of interactive prototypes that successively address core issues in this particular setting. Finally, the problems and issues pertaining to this setting is presented and identified. The main contribution of this paper is that it, by pointing out problems and issues related throw-away prototyping with sensor-intensive systems, extends the design cycle of the original design science framework. This is determined to be a necessary step in order to address the inherent multi-disciplinarily of sensor-intensive HWID systems.

Keywords: Sensor prototypes, design science, HWID, embedded systems

1 INTRODUCTION

In this paper, we describe the application of the design science framework [3] for the use of interactive, sensor-intensive prototypes to develop greenhouse climate management systems. Consequently, this study emphasizes possible problems and issues when applying design science to indoor greenhouse climate management performance through the utilization of sensor network technology.
We identify the need for specific design science framework to address the complexities of HWID sensor-intensive systems and we provide a case study, as our contribution, as a way to test this framework.

In order to contribute to the body of knowledge on environmentally sustainable HCI [22] and environmental informatics [1], we propose in this paper to approach HWID as a kind of design science. This HWID-as-design-science-approach then forms a representation of a design space a new work system that can be used as a point of reference for further relevant work. Our research questions are:

1. What new utility does the interactive climate management system provide?
2. What kind of sensor-intensive prototypes demonstrates that utility?

We use these questions for guidance in our case study into interactive greenhouse climate management and control, while keeping track of the problems and issues we encounter during the execution of the five prototyping rounds.

2 BACKGROUND

As the importance of eco-sustainable growth becomes increasingly important, the human-computer interaction and micro information systems research communities must address environmental sustainability challenges. This paper has been inspired by recent developments in design science research as described by Hevner, March, Park and Ram [3]. Design science research (DSR) is an approach for evaluating novel artifacts. Therefore, it is different from traditional research that mainly directs attention toward observation and analysis. A DSR project creates an artifact that is then assessed with regard to its contribution to rigor and to relevance. The researchers use scholarly literature to form theories regarding the DSR artifact that is created. The ultimate test is the proposed relevance for use with practitioners.

In line with common DSR principles, we want to design our artifact but doing in a way that optimizes end-user relevance and subsequent published contributions to the academic knowledgebase. A part of this is to be able to reproduce prototypes and user-oriented evaluations of them. We propose to use what we call “throw-away” sensor-intensive, interactive prototypes. We suggest that reproducibility in throw-away sensor-intensive prototypes can be achieved by using re-buildable Lego NXT prototypes with instructions in terms of video clips showing how to build the prototypes.

There are examples of DSR within neuroscience [2] and in sustainability research, such as Watson et al.’s environmental framework [1] using the design science guidelines provided by Hevner et al. in their seminal MIS Quarterly article, “Design Science in Information Systems Research” [3]. In this paper, we focuses on the Design Cycle of the three cycles belonging to the DSR framework. Thus a deliberate limitation of this case study is that we do not consider the rigor and relevance cycles. This may be better addressed in future work.

DSR has been proposed to test the proposition that incorporating user modeling and usability modeling in software requirement specifications improves design [4].
and more generally, Human Computer Interaction has been suggested as a design science discipline [5].

2.1 Sensor Intensive Work Systems

The embedded and sensor context for this paper is greenhouse monitoring systems and management of same. Research in this area focuses on sensor-intensive systems [6]. On an even wider scale, OECD [7] presents sensor technology as a fundamental enabler for addressing global challenges with regard to global warming.

We conducted this particular evaluation using a design science framework [8-10] that shows how it is possible to incorporate the notion of sensor-intensive systems into existing frameworks. Our focus here is on rigorous design, as listed by the 5th Design Science guideline published by Hevner et al. Our artifact-driven approach in is addressed in the first DSR guideline: Design as an artifact. The instantiation is a demonstration of the usefulness of the generate/evaluate method.

We recognize the importance of other disciplines; two such examples are decision support systems [11] and embedded networked systems [12]. Design science, as discussed in IS [13], guides the design of the artifact and the constructs, models, methods, and instantiations that sum up this meta-artifact.

At that point, the demands and needs for our prototypes are mostly related to size, form, and function for the designed artifacts. The design theory nexus is able to cope with multiple requirements [14]. It forms a method for a multidisciplinary approach to design science studies within HWID systems of this complex nature. We monitor the prototyping efforts and then discuss the possible need for this more elaborate design science method called the design science nexus.

In relation to design science, HCI has, for long, been conceived of by some researchers as a design science [16]. The iterative cycle of generate and evaluate designs of design science is at the core of HCI’s user-centered design [4, 5]. However, the importance of combining embedded sensor-intensive systems with consideration of users’ interactions with such systems has appeared more recently [17]. Within the climate control community (not in the HCI community), Van Straten et al. [18] proposed that the interactive use of sensor-intensive information about crop growth would allow greenhouse control strategies to become more optimal in an economic sense. Both long-term and short-term dynamics of the crop and greenhouse and external weather conditions could be considered in such interactive control strategies. However, a major challenge in the development of interactive control strategies is the lack of reliable crop development models for the wide variety of crops encountered in real settings and the consequential need for a sensible allocation of tasks for the human grower and automatic control systems. One proposed solution is a two-systems approach, an interactive sensor-intensive control system for day-to-day climate control, and another more decision- support-like system to consider the long-term effects of climate management on crop production [18]. Within such a grower-oriented framework, the grower interacts with the system by setting constraints on temperature, humidity, and other evapo-transpiration variables over a period of interest. The grower is supported by a model-based simulation system that predicts
how these settings influence energy consumption, photosynthesis, and condensation [18].

In the HCI community, related work has been done by Pearce et al. [19, 20], who studied interactive gardening. They wanted to use what they called “everyday simulations” to allow non-specialists to experiment with and in an interactive way learn optimal strategies for watering gardens. In order to develop such a tool, they noticed “…the absence of design processes specifically tailored to this type of project…” [20], and suggested areas to consider in terms of developing a design process for such a tool. Among the identified challenges were how to allow HCI designers to develop a necessary level of understanding of the horticultural domain and in particular how to do this within a reasonable time period. The solutions included letting the domain specialists automate a large number of decisions and allowing the end-user to only gradually take part in the decision making as he or she becomes more knowledgeable. Secondly, the HCI designers tried to embody material constraints in the design, as suggested by work domain analysis [21]. In the end, they designed a software tool called SmartGar denWatering, which works as decision support for gardeners when defining watering schedules and use. In a study of 20 gardeners using the tool, the researchers identified issues of trust and confidence in the underlying horticultural models and their interactive use. They concluded that the outcome of the interaction with the software should not challenge “idiosyncrasies in existing practice” [19, p. 224] and that gardeners wanted models with higher granularity than those provided by the tested system.

More generally, the whole idea of designing interactive systems for sustainable environments and global climate management has been outlined by leading HCI researchers. Dourish [22] took the opportunity to explain how ICTs can be used to promote environmental sustainability on the part of IT users, but also warned that current HCI research is not sensitive enough in reference to the political and cultural contexts of environmental practice. The idea has also found support in the IS community, where researchers have proposed that information system design can be a catalyst for environmental sustainability as an expression of value-sensitive design [23]. Thus, the role of IS design in developing interactive systems for sustainable environment is being pressed in both IS and HCI communities. So far, most of this work has been on a grand scale of proposals, but the first steps toward meeting the new challenge in the creation of interactive systems, environmental sustainability, have been taken, e.g., [24]. However, rather than focusing on the grand global climate management challenges, in this paper, we report from the perspective of a micro-climate control (greenhouse and plants) research project [25].

METHOD

We introduced design science in the background section. From this framework, we extracted the generate/evaluate activity [3]. The reason for doing so was the need for a clear way of capturing the problems and issues related to throwaway prototyping.
The separation of generate and evaluate activities is useful because it allows us to assume clear roles in each sequential prototyping effort. Moreover, we do not necessarily assume the same roles across all sequential prototyping efforts. This is later demonstrated to be an important driver of complexity. In the very beginning, the HCI researcher may create throw-away prototypes using paper or clay. Later in the process, it could be that the HCI researcher is now in the evaluation role, while the other researcher generates electronic prototypes using Lego Mindstorms NXT. What separates these two activities is that each prototype is evaluated and the feedback is used in subsequent prototypes. The HCI evaluation activity covers both an activity where the HCI researcher is acting as an end user and, later, the HCI researcher will act as part of the design group which is sitting in the generate/evaluate new box.

In Figure 1, we describe how evaluate and generate activities are the two processes in which we intervene by recording the problems and issues we encounter for each prototype we create. That is the subject of the following section. Each of the generate processes outputs a prototype which is then evaluated. This process is repeated, and the prototype is matured over time.

3 CASE STUDY WITH THROW-AWAY PROTOTYPES IN SENSOR-INTENSIVE HWID SYSTEMS

For each of the prototypes we note down the problems we encounter for later discussion.
3.1 Prototype 1 – proof of concept

The first prototype was a ”proof of concept” prototype. It was a simple text-output prototype that served to show that it was meaningful and technically possible to make an interactive sensor-intensive prototype to conduct climate management. The prototype was evaluated by internal discussion in the research group using a generate/evaluate tool with the aim of conducting a rigorous evaluation. We decided to go on with the LEGO due to its ability to connect to the minds of many people with little technical knowledge and its flexibility in programming capacity, both of which had previously been demonstrated [8, 9].

![Fig. 2. IT Grows prototype 1 – demonstrating sensor-based climate management prototyping with Lego Mindstorms](image)

**Fig. 2.** IT Grows prototype 1 – demonstrating sensor-based climate management prototyping with Lego Mindstorms

![Fig. 3. Lego Mindstorms NXT as the platform for prototyping](image)

**Fig. 3.** Lego Mindstorms NXT as the platform for prototyping

Lego Mindstorms NXT is the unit that we used to model the sensors and the actuators (motors). The unit has four input sensors, which are in the standard kit: touch (shown in Figure 3), light, sound, and a distance sensor.  

**Problems encountered:** The most predominant problem in this first phase is the individual differences between the researchers which created the prototype. It was not clear if a researcher was speaking/thinking as an engineer, physiologist, or something totally different.

3.2 Prototypes 2 to 6

We have worked through five more prototypes: Prototype 2 through Prototype 6, and noted the following problems/issues:

- **Prototype 2 - Model of greenhouse**
  - **Problem:** The model turned out to be too complex for the need of the end user, which was a company involved in the project. It was stripped of its sensors and control systems.

- **Prototype 3 - Simulated plant table**
  - **Problem:** There was differences between what the domain expert thought was possible and what could actually be done with the Lego Mindstorms NXT kit

- **Prototype 4 - Sketches of model greenhouse simulation**
  - **Problem:** We lacked some clarity because of the static nature of sketches. A dynamic prototype would have been of better use.

- **Prototype 5 – Light sensitive resistor**
  - **Problem:** We were not clear here in relation to which aspect of the design that was addressed. It was mainly the computer related
aspect, and not the interaction part, but that was not clear until afterwards.

- **Prototype 6 - Decision support part of system**
  - **Problem:** A significant change of focus occurred here, and it is not completely evident how this fits with the first prototypes. A need for “some other way” is now quite clear to the researchers.

Each prototype represented a different design task. Prototype 2 was made to demonstrate that the prototype was easy to disassemble and reassemble in new contexts and that it would allow different users and other stakeholder groups to interact with the prototype. The third prototype was aimed at generating relevant functions that would allow greenhouse growers to interact with real sensor data. The fourth prototype was made in order to interact with a greenhouse grower consultant. Prototype 5 was developed with the purpose of simulating the more realistic scenario of managing several sensors from several greenhouses. Prototype 6 was a high fidelity prototype of a part of the to-be-designed climate management system, with a so-called the “side-bar” which gave decision support to the grower based on model simulations of the climate. The results of the cognitive walkthrough were sent to the developers, who stated that some results – that is, some design suggestions in reference to consistency, level of detail, and scalability of graphs were particularly useful in the further development of the system.

### 4 DISCUSSION

We have described selected parts of a development flow of a sensor-intensive prototype within a DSR generate-evaluate process (Figure 1). For each of the prototypes we identified a problem. Table 1 provides an overview.

The use of LEGO Mindstorm as a sensor-intensive prototyping tool is, we believe, the first attempt to make “throw-away” sensor-intensive prototypes that are easy to assemble, disassemble, move, and re-assemble. In that way, we were able to reproduce the different LEGO Mindstorm sensor-intensive prototypes. Hence the evaluation results can potentially be repeated and easily reproduced by other researchers.

The “throw-away” nature of the prototypes, that is, the easy reproducibility of the sensor-intensive prototypes, may, among other considerations, provide a solution to the problem raised in related HCI research: How to allow HCI designers to develop a necessary level of understanding to design relatively simple user interfaces for complex work domains [27], such as the horticultural domain, and, in particular, how to do this within a reasonable time period [20].

Climate management and climate control overlap in our proposed combination of micro-IS and HCI approaches to greenhouse climate. Thus, we accommodated the proposals [18] to allow growers to use a two-system approach.
In operational climate management, the actions taken by the one(s) using the systems are dependent upon timely readings of temperature, humidity, light intensity, etc. Lego Mindstorms provides these readings and, thus, it provides the dynamic picture which is a requirement of such systems. Furthermore, Lego Mindstorms can control the greenhouse prototypes with its motors. We have used the motors to simulate the opening and closing of curtains.

4.1 RESEARCH CONTRIBUTION

We have demonstrated the usefulness of using a design science research framework approach to capture and identify problems when conducting HWID with throw-away prototypes. A special valuable property of our approach is that we are being explicit about the roles that are assumed by each type of generate/evaluate activity throughout the process. This allows for the creation of a lightweight log book of how a project develops over time and the possibility of going back in time to restart the design at a given point.

The design science research framework has provided us with an established research knowledge base from which we have focused on the generation of prototypes and the subsequent evaluation of same. We have noted who conducted the creation and evaluation at each point in time.

Sensor-intensive prototyping involves electric engineering and computer science in addition to HCI and end user involvement. From the set of noted problems we have identified an important aspect of the throw-away prototyping effort. This can possibly be further researched using the Design Science Nexus by Heje & Baskerville [14].

5 CONCLUSION

The first research question, what new utility the interactive climate management system provides, could not answered in full by the research reported here. However, the LEGO Mindstorm prototypes identified the utility of the to-be-designed climate management system in terms of providing possibilities for allowing growers to participate in the dynamic location of sensors out in the greenhouse. This was a unique finding related only to the use of LEGO Mindstorm prototypes in the case.

The second research question, what kind of sensor-intensive prototypes demonstrates that utility, was answered by identifying the possible problems and issues when using sensor-intensive throw-away prototypes in the design cycle. Thus the application of a design science framework for combining micro information systems with human-computer interaction approaches adds structure to the design process. Furthermore, we have been able to point out a multidimensional DSR framework that can be used in subsequent research.

By adhering to a lightweight process that concentrated on the generate/evaluate process, we were able to undertake a series of prototyping efforts over a period of 18 months and keep track of the progress. The relevance of the “interactive, sensor-intensive prototyping” approach has been confirmed by the exhibition of one
prototype at a large agriculture exhibition. The rigor has been described in terms of
design science, micro information systems, and the ability to reproduce sensor-
intensive prototypes.

ABSTRACT
Although automation has been introduced in all areas of public life, what seems to be missing is a reflection at the organizational or societal level about a policy of automation. By this we intend appropriate declarations made at the level of rationale, future plans and strategies to achieve intended goals and most importantly how those achievements will impact on various aspects of societal life, from legal responsibilities to moral and socio economic issues. In some public spheres these issues are becoming quite controversial because automation opens up possibilities of profound structural reorganization; however, we lack a discussion across and within different work domains to help us review methods or even methodological principles needed to gather and organize knowledge towards the construction of automation policies. This paper uses the UK service organization for Air Traffic Management Domain called NATS – National Air traffic Service, as a case study to illustrate an example of an organization currently undertaking critical self-reflection about automation policy or lack of such, along with the illustration of some unresolved deep concerns raised by the development, introduction, and continued use of automation.

INTRODUCTION
Although automation has been introduced in all areas of public life, from production to tertiary sectors, what seems to be missing is a reflection at the organizational or societal level about a policy of automation. By this we intend a declaration of rationale, future plans and strategies to achieve intended goals expressed not longer at a single mission level such as gate-to-gate trajectory management, but how those achievements will impact on various aspects of societal life, from legal responsibilities to moral and socio economic issues. While in some public spheres these issues are becoming quite controversial because automation opens up possibilities of profound structural reorganization, we lack a discussion across and within different work domains that help us to review methods or even methodological principles needed to gather and organize knowledge to the construction of such policy. For example, current concerns about the deep changes to be introduced in the British Public Health sector would likely benefit from a more open discussion about the relationship between automation and higher level societal goals (see Rozzi et al., 2010).

This paper uses NATS—National Air Traffic Service, the UK Agency for air traffic management as a case study to illustrate an example of an organization currently undertaking critical self-reflection about automation policy.

A previous version was presented at ATACCS 2012, 29th-31st of May, 2012, London, UK.
along with the illustration of some unresolved deep concerns raised by the development, introduction, and continued use of automation. Before discussing NATS-specific concerns we shall briefly review major issues within the cognitive ergonomic literature about the relationship between automated processes and human control.

**Major pitfalls of the automation process**

Information and computer technologies provide an increasing number of opportunities to develop new solutions to assist operators/professionals across many domains of practice in managing complex socio-technical systems. There are, however, a number of concerns highlighting complexities and paradoxes embedded in the automation process. Bainbridge (1986) discussed the unexpected consequences of technology-driven automation which often relies on human reliability to be safely operated. One of the “ironies” is that automated systems are often introduced on the ground that humans are less reliable than automation because of “intrinsic” limitations in their ability to monitor for unexpected, unsafe events in a stream of a routine flow of events.

Paradoxes linked to the introduction of expert systems have been extensively emphasized (Billings, 1991; Norman, 1988; Woods, Cooks & Billings, 1995, Sarter & Wood, 1997). Inappropriate design choices might result in an increase of operators’ workload, in an excessive demand on working memory, in a difficulty to cooperate with team members, and finally it might slow down the development of expertise (Sarter & Wood, 1997). Automation is expected to assist operators in achieving the overall system goals in a more cost-effective way. These expectations have, at times, relied on a number of mis-beliefs (Mosier, 1996). In fact, although it might lead to “de-skilling”, automation does not decrease the requirements for expertise. Some have nevertheless been led to believe that expert systems can replace the need for or even decrease the standard of expert operators.

This claim does not consider that automation has to be constantly adapted to its operational context to be effective (Vicente, 1999). This is because expert systems have a limited scope with respect to the variety of objectives characterizing activities in complex socio-technical systems. This variety reflects the ability of expert operators to identify ways to improve the system performance in routine situations. The role of operators when interacting with complex technical system has often been emphasized in relation to their ability to manage exceptions. While this is true, it should not be neglected the finding that operators systematically go beyond the prescribed practices to enhance system’s efficiency (Wright & McCarthy, 2003). An old study involving observations of maintenance operators, reported that almost one third of the times operators have been observed making an informal use of available tools (Leport, 1970). By informal it is meant that the tool is not used for the purposes it was designed but rather with the intent of making the corrective action more effective.

This phenomenon has already been well documented and studied within the francophone ergonomic tradition quite long ago (Cuny, 1979, De Keyser, 1991, Leport, 1970). The informal use of tools and procedures reflect often a search for an improved efficiency, not just a solution to unexpected problems. Similarly, the spontaneous generation of linguistic code has been observed in different operational settings (Cuny, 1979). Notice that deviations from standard communication patterns have generated fatal misunderstandings such as in the case of air traffic controller / aircraft pilot radio communications (Mell, 1993, 1994). In spite of these fatal accidents, deviations from standard use are often generated with the aim of achieving task goals. In this respect, automation should support operators in finding the best way to achieve the goals while limiting the negative consequences of possible misfits between tools adaptations and task constraints and goals (Vicente, 1999). As part of the integration process operators will engage in «finishing the design» of the tool with
respect to its original intended use (Rasmussen, 1986), i.e., improving the fitness between the tool and the complexities of the operational environment.

**Automation and information processing stages**

In an attempt to characterize automation with respect to models of information processing, Parasuraman, Sheridan & Wickens, (2000) have used a simplified model of human decision making and problem solving. The model allows the classifying of technological innovations according to four stages:

- (i) information acquisition;
- (ii) information analyses;
- (iii) decision selection;
- (iv) action implementation.

The introduction of new technology might interact with cognitive processing in each of these stages with differing degrees of automation. The allocation of tasks to humans and machines depends then on the level of automation chosen. While the classification schema does offer a means to group technological innovations across different domains, guidelines for function allocation do not seem straightforward. Criteria for deciding how to do task sharing have to be based on an understanding of the impact of automation on the targeted communities of practitioners. Neglecting, for example, the crucial role of cooperation or adaptation processes like "finishing the design" does not seem a very promising start for deciding on task allocation. Further, such a simplified model of human cognition and of human-computer interaction might mislead designers and engineers to believe that a fairly simple algorithm can generate the desired answer to a very complex and still unsettled issue (see also Dekker and Woods, 2002). Some examples discussed below will illustrate the pitfalls of such naïve assumption.

For example, automation concerning the (i) acquisition and (ii) information analysis stages involves the organization of incoming sensory data. A stated purpose is to decrease attentional demands of operators by highlighting or cueing relevant information while leaving the rest uncued but still accessible. Yet, this apparently simple solution neglects considering a number of issues. The assumption here is that human information processing capacity is limited and thus the number of items that can be processes at anytime cannot exceed that capacity. While this is not wrong, this statement neglects considering that there is no an obvious way of “measuring” that capacity as it is subject to people’s expertise, organization of labor and the development of new working practices. In addition filtering “relevant” information raises the issue of “context sensitivity” (Woods, Patterson, & Roth, 2002). What needs to be noticeable depends on the situation which includes other related data, the “history” of the process, the intentions and expectations of the observers (Mumaw, Roth, Vicente, & Burns, 2000).

A higher level of automation within the information analysis stage implies the temporarily or permanently hiding of certain information. For example in Air Traffic Control (ATC), certain electronic displays of future traffic problems “hide” or “reveal” information according to the role of operator within the team. Or, the available data might be automatically organized in terms of problems to be dealt with in a given priority order. Notice that information filtering, problem formulation and priority assignment, all involve anticipating how the system under control is going to evolve. Automation of some anticipatory functions is then involved in the design of predictor displays introduced in both the flight deck and ATC to assist operators to project future courses of flight.

Automation interacting with the third stage of decision making leads to the selection of a course or several courses of actions. Automation here might assist operators in calculating the best option(s) given the constraints of the current situation. For example the Flight Management System (FMS) in the cockpit can, more effectively than pilots, calculate the most cost-
effective trajectory in terms of gas consumption and timing.

In ATC, decision aids assist controllers by offering solutions to traffic problems and in this respect several systems have been proposed and evaluated (e.g., ERATO, HIPS, URET, IFACTS) (Mendoza, 1999). At this level of automation a range of alternatives are proposed, leaving operators responsible for making the final choice. A more advanced automation would give very little or no choice to operators as to what solution to implement. This implies automating the process of evaluating costs and benefits associated with each alternative. The problem is that the criteria used in the automated evaluation process are not likely to include all of the factors affecting human decision-making. In fact there will always be a number of conditions where the proposed solution would need to be adjusted to reflect local contingencies. Therefore it seems crucial that a high degree of automation at this stage of decision-making, leaves open the possibility of deciding whether or not to implement the course of actions. For example a number of studies on Traffic Collision and Avoidance System (TCAS), have shown that pilots do not always comply with the advice provided by the automation (Amaldi et al., submitted; Garfield, & Baldwin, 2004) unless they can verify its compatibility with external conditions. Notice that improving an understanding of the criteria underlying the solution proposed facilitates a complying behavior (Lee & Lees, 2007; Pritchett, & Hansman 1997).

Automation intervenes in the last stage of decision making through the implementation of the course of actions. For example digital data link will allow air traffic controllers to automatically uplink a pre-edited clearance into the plane’s FMS. Notice that the clearance could be a computer-selected option to an automatically identified traffic problems. Current proposals to uplink ACAS to FMS are another example.

What is automation for?

What is then automation? It is a transformation of a world state accomplished by an electro mechanical device with or without human intervention. Our previous discussion aims at classifying the level of the involvement with humans with respect to cognitive operations involved in decision making.

What is automation for then? It is the means by which we extend our cognitive skills; by which we aim at increasing the resilience of the operational system (by introducing for example, back up sub-components); by which we aim at increasing productivity by enabling the system with new tools that increase the throughput.

What can be automated? There have been cases, in the history of R&D in Air Traffic Management when (over) ambitious automation projects have been withdrawn. Lack of mature technology or too many contingencies that made it impossible to proceduralise operational practices. One apparent rational was that whatever could be made faster and more reliable through the use of automated device, it should.

For a few decades, ATM operations have been the object of R&D efforts to make them faster and more reliable through the introduction of automation. There was a lack of consideration of the wider impact of those innovations. For example, increasing traffic throughput en route was not connected with the need to increase airport capacity. Increasing airport capacity, however, has been the target of serious environmental concerns.

Starting on the assumption that the complexities of current system require automated aids, the coupling of computers to air traffic management has surely resulted in an increase of safety and productivity. Nowadays targeting individual human limitations with respect to system control is not longer a viable strategy for expanding current business. The main challenge seems to have shifted from designing interfaces usable or trustable (although these are still serious concerns) to mapping out the added complexities and the profound consequences of the
technological innovation process. For example, recent debates by environmentalists have challenged that Civilian Air Traffic is an important contributor to CO2. To what extent, then any technical innovation could be planned to address the pollution of the atmosphere? The main point to be raised is that the human-computer interaction unit of analysis has to be embedded in a larger context to target limitations and contradictions of the entire system, rather than marginalizing the human as the ‘limiting factors’ to system development.

Organizational culture in NATS

This is a study about NATS organizational culture. In particular what are the existing views and expectations held by the middle layer management, toward the increasing dependency on digitised information processing systems? By doing this investigation we wish to articulate the model of cultural analysis suggested by Silbey (2009) and a number of researchers working in the area of organizational cultural analyses (e.g., Bergström, Dekker, Nyce & Amer-Wåhlin, 2012). Culture, safety and safety-culture, have been treated as ‘components’ of systems and as such discussed as either the source or the cause of behavior. Further isolating components prompts researchers to treat them as measurable and manipulable to control on their ‘effects’ on system behavior. We are basically seeking to advance our understanding of the main claims of what a cultural analysis is NOT: (a) culture as causal attitude as the engine that pushes processes; (b) culture as engineered organization, proposing a set of indicators that verify the cultural recommendations have worked. Rather, we support the view that culture is to be understood as in a dialectic relation with practice, one cannot be constituted as an object of study without the other. Their relationship is not one of cause-effect but rather one of mutual dependency. In other words, we can’t study safety culture without inquiring into those regular patterns that characterize organizational behavior. The safety culture literature, on the other hand, hardly makes reference to the following features of organizations: (i) power, (ii) group interest, (iii) conflict or (iv) inequality.

These features (organisational) are feeding the following cultural schema and interpretative mechanisms:

- Normative heterogeneity
- Competitive and conflicting interests
- Inequalities in power and authority

What is missing from a number of account on safety culture is a focus on process that produce systemic meanings where isolated factors like understaffing, excessive workload, lack of effective communication are seen as a constituent part of a general pattern ... Within the interpretative schema of a cultural analysis, these factors are not caused by a ‘wrong culture’ but they are a constitutive part of it, give and take meaning from it. They become ‘dysfunctional’ only when clashing with public images or other competing interests. Manipulating these factors as though they are independent from the historical-cultural context that did not simply produce them, but from which they derive their intelligibility and at the same time ‘feed in’ a more general patterns, is not very promising. Normalizing deviance, informational secrecy, credibility gap, are examples of mechanisms that constitute cultural schema.

Is NATS enacting a moment of critical self-reflection to unsettle what is taken for granted and make space for innovative practice?

NATS MAIN CONCERNS WITH AUTOMATION

NATS is currently reviewing their position and their implicit assumptions with respect to automation. At this stage NATS is seeking views in the face of unexpected side effects linked to increasing complexities from all parties involved in the design, implementation and use of the existing or planned automated systems. Such process of critical self-reflection aims at enhancing its resilience in the face of increasing complexities linked to ongoing technological innovation. The notion of organizational resilience has become popular in the area of
organizational risk management (Hollnagel, Woods, et al. 2010). The more an organization builds its own resilience, the more is capable of adaptively responding to hazardous events. We extend the notion to situations where the planning of far reaching changes cannot indeed account for in advance for all of its major contingencies. Given the increased complexity introduced by more and more powerful technology, NATS attempts to move from a rather patchwork to a more holistic approach seems worth reporting. In the following we report a two-stage data collection aiming to document NATS main concerns, suggestions, recommendations to the problem of lack of automation policy.

**Method**

The main objective of the data collection was to elicit subject matter experts a wide as possible range of issues deemed to be associated with past practices of automation development and introduction into air traffic control management. Data collection was divided into two stages.

First in December 2011 we devised a survey and distributed it mainly to NATS officials. Three main themes were suggested as guidelines but then individuals were encouraged to raise any other issue and think about in terms of

a) What the problem was—the problem statement

b) Why was it a problem

c) What needs to be done about it

The guidelines for reflection were centered around three main themes:

i) What is NATS scope and vision for automation;

ii) What is the role and responsibility of the human;

iii) What are the skills that need to be developed and maintained.

Second, we organized a Workshop in April 2012 attended by approximately 70 people partly from NATS and partly from a number of disparate industries. Participants were asked to participate in 4 activities designed to encourage constructive and creative thinking about automation and how it should be developed, deployed and utilised. For each of these activities the following provides a brief definition of their aim and the opening question used to initiate the discussion

Activity 1: *Reversal*. Aim: elicit recommendations for improvements through identifying weaknesses. This is done by asking the opposite of the question you want to be answered, and then by reversing the results as appropriate.

Opening question: *What things can we do to make the introduction of Automation less likely to succeed and less likely to be safe? How could we make it worse?*

Activity 2: *Reframing Matrix*\(^2\). Aim: Looking at problems from different perspectives. The proposed perspectives were Pilot; ATCO; SRG and NATS although groups were free to select their own perspectives.

Opening question: How should we prepare for the introduction of Automation in NATS?

Activity 3: *Brainstorming*: Aim: Participants were asked to elicit solution to the following:

Opening question: What actions should we take to ensure Automation is introduced safely and avoid the problems we have discussed?

Activity 4: *Force Field Analysis*\(^3\): Aim: Understanding the pressures for and against change. Participants were asked to select ideas from their brainstorms for force-field analysis.

---

\(^3\) Adapted from [http://www.mindtools.com/pages/article/newTED_06.htm](http://www.mindtools.com/pages/article/newTED_06.htm)
The stated objectives of the 4 activities were:

- To validate the draft ‘Use of automation in NATS operations’ position paper by exposing it to expert scrutiny
- To identify enablers and blockers to the delivery of an effective policy on automation within NATS
- To identify problems with introducing automation within NATS and create potential solutions to these problems
- To engage experts (from around NATS, the UK and the world from Aviation, Regulation, Medicine, MOD, Academia etc.) to form a community of expert resource
- To identify the risk landscape regarding automation and thus provide a metric against which safe introduction of automation can be assessed

Findings

Stage One: Generating problem statements

In reply to the survey, NATS has compiled 14 statements that we grouped into 6 groups.

Group Statement 1. Lack of definition/vision: There is not an agreed set of definitions about the scope of automation, i.e., to what extent is mostly technology- or problem-driven. This results in confusion and lack of clarity in planning and communication. Different people have different expectations and different requirements regarding what automation will deliver. Similarly there is not a single agreed vision for automation. The scope of automation needs to be defined and agreed. Automation affects every aspect of the business – it determines how people are selected and trained; how many people remain in the system and NATS’ capacity to generate income. There is no clear definition of the future levels of automation that NATS should be planning for.

Group Statement 2. Responsibility and role allocation. No single clear picture of how automation will affect MOPS\(^4\) – in particular the responsibility of the operational staff for the decision making process. The literature previously reviewed suggests how automation can interact with the problem solving and decision making process. The introduction of new automated technology will affect the role of the human. It is vital that human strengths and vulnerabilities are accounted for in the design and attribution of roles. Also, it is vital that the resulting role is one that can be trained for.

Assumptions about role allocation are being made at the moment and are affecting how NATS plans and implements projects but these assumptions are not being made explicit.

The allocation of responsibility between the machine and the human needs to be defined clearly and explicitly over time and at each key milestone of system operation.

Group Statement 3. The introduction of automation will be neither as safe nor as effective as it could be. Automation could be used to remove risks from the current operation – unless this is done in a focused way (aimed at specific known risks) the full benefit will not be realized and, in fact, automation may add risks. Automation needs to be focused upon removing key risks from the operation and exploiting the different strengths of the human and the machine.

The operational effectiveness of our systems relies heavily upon the close relationship between the human and the machine – if this is not optimized then maximum effectiveness will not be realized. Automation needs to be focused upon achieving the most effective balance between human & machine. The cost/benefit balance of automation needs to be managed.

Group Statement 4. There is no clarity on how the relationship between the human and machine will change due to technical failure (or cyber-attack). Current assumptions regarding the capacity of the human to revert to manual operations are likely to

\(^4\) Minimum Operational Performance Standard
prove incorrect after a short while of automated operations. If this is the case, we might not have a mode to revert to.

It is difficult to place limits on the extent to which automated systems should be implemented in order to ensure that they ultimately remain under human control. In general, the greater the level of automation the further the human is removed from the control loop and therefore the harder it is for them to recover control. The skills that the human will need to exercise in order to effectively participate in Human-Automation interaction need to be identified and the impacts of automation anticipated.

Group Statement 5. Aspects of human behavior indicative of their ability to effectively use future automated systems are not receiving the emphasis required. We do not yet know the number of people and the types of skills/capabilities we will need to provide for the future ATM changes. These have been planned over the next few years and will require current controllers to significantly adapt their ways of working. The extent to which they will need to be helped to do this will depend on NATS ability to effectively assess their automation “competence”.

Group Statement 6. There isn’t yet an agreed and validated methodology for assuring the performance of the automated system (cooperative performance of human and automated technical system). Co-ordinate/co-operative requirements are neglected. As automation levels increase, the complexity of the emergent system interactions will also increase. Traditional methods of analysis and validation are unlikely to provide sufficient assurance that the system will be stable. It will be necessary to set and measure demanding performance standards for the total system.

NATS is planning for levels of automation that have not yet matured into operational systems. They might not mature. Automation of human-centered socio-technical systems has far reaching consequences that can be framed only at an organizational/societal level (see Rasmussen and Svendung, 2000)

Stage Two: Automation Workshop

There was considerable overlap between the statements generated in the two Stages, analysis of respective contents and overlap is ongoing. At the moment we have compiled a table including the frequency at which a number of suggested activities have been suggested in order to cope with present and future challenges of automation.

[Note: we have a thirds phase with new data coming from another W/shop. Data fully transcribed and now under analysis]

Table 1. Most commonly elicited activities to cope with automation challenges

DISCUSSION AND CONCLUSION

We looked at NATS current critical reflection upon automation and its consequences as a case study of engineering resilience against unexpected and undesirable effects of automation. Given the initial stage of the work, our conclusion takes the form of a working hypothesis to be further confirmed. Given the increasing complexities of socio technical systems, traditional HCI and human-automation interaction issues cannot be handled outside a general framework of automation policy. This includes a set of goals, values, costs and strategies to cope with uncertainties and unintended effects of automation. First, NATS needs to address more explicitly what the long
term and scope of automation is going to be. This goes beyond a piecemeal approach where automation innovation would be technology and task driven. The latter means that two main rationales for introducing automation i.e., availability of the technology and a focus on a specific (set of) task are inadequate. In fact the assumption that interventions on subcomponents of the system do not need to consider the long term effects on the operations in their ensemble, seems under scrutiny. However as we stated, as automation level increases, the complexity of the emergent system interactions will also increase and traditional methods of analysis and validation are unlikely to provide an overall assurance of system stability.

Second given a better specification of NATS requirements and expectations about automation, what will be the range of roles that humans are expected to engage with? The history of automation both in the cockpit and on the ground has shown that humans act as ‘mediators’ (Downer, 2009) between the automation and the environmental contingencies and operational complexities. Typically operators have to monitor for un-expected interactions among apparently unconnected subcomponents. Further they need to reconcile the need for standardization (like the European Sky) with the need to locally tailor tools and procedures.

Third, what sort of competencies will be required; how they will affect the selection process; the training and the maintenance of them has to be informed and guided by a policy of automation. This goes beyond the specific characteristics of the system in use. For example, a recent study by Amaldi & Rozzi (2012) has documented that in the case of a National Service Provider, a vision of automation has affected decisions about changes on a specific interface and thus about competencies required in an interim phase.

Fourth, safety has reached level that can be hardly improved through the development of further safety nets alone. Rather the roles played by the various agents across the organizational levels of control have to be openly discussed, identified and defined.

Abstract.
This paper first discusses two cognitive science paradigms and then present
third approach related to interaction with the world as known as embodied cog-
nition. The focus is to analyze work settings with the help of cognitive work
analysis and human work interaction design approaches. The case of power
plant control room is discussed and analyzed in the context of human system in-
teractions, work and task analysis. This approach helps in reducing cognitive
workload on operator which can result in reduction in errors in managing the
control room of the power plant.

Keywords: Cognitive Work Analysis, Embodied cognition, Human Work In-
teraction Design, Power Plant Control Room, Ecological Interface Design

1 Introduction

In the year 1956, two different conferences and seminars gave birth to
two new research areas known as Artificial Intelligence and Cognitive
Science. They stress that brain functions like a computer that specifies
symbols can be processed and manipulated and known as cognitivism.
This view that thought is manipulation of abstract symbols, algorithmic
computation in the same way as computer does. All meaning arose via
correspondences between symbols (words, mental representations) and
things in the external world. The mind was seen as a mirror of nature,
and human thought as abstract and disembodied. Therefore, in prin-
iple, a computer could replace a brain, and in particular computers can
do anything that brains can do. But this give rise to symbol grounding
problem and unable to explain how we get meaning of objects.
The two main approaches (symbolic and connectionist) study cognition of an individual being but as we live in the world, environment and interaction with others play an important role. This thinking leads to theories of embodied and situated cognition, where cognition is seen as taking place not only in the brain, but also in interaction with the world supported by the body [1], [2]. Moreover, this may suggest that neural processes not only generate sensory experiences, but also help in exploratory interaction with the world that guides action or behavior. This paradigm finds applications in various research projects notably robotics, autonomous agents, and interactive interfaces [3], [4]. This requires awareness of the relationship with the world especially work, physical movement, action, and other affective behavior reactions. Everyday human activities include all of above states that we can understand through work analysis, and embodied cognition – both are prominent paradigm in cognitive science. Embodied cognition, CWA, and Cognitive System Engineering (CSE) [5] provide a new framework for Human Work Interaction Design (HWID) research. A more detailed HWID framework is given by [6] (as shown in figure 1).

Fig. 1. A Framework of HWID [6]

To represent organizational settings that describe work processes we need to understand role of information and functional demands of the
dynamic work environment. Mapping of information to features must show underline semantic structure of the work domain. This require nesting of information which implies meaning inherit in the work processes. For this, we require knowledge and understanding of objects. Objects are those with which we deal in everyday world. How we acquire the meaning and refer to the symbol or sign. Informatics and cognitive science deal with problems representation, semantics of computation and their application to create technology.

2. HWID Framework for Control Room

All this depends on perception of objects and conception of object that has been embedded in commonsense discourse. Mental phenomena, spoken & written language, and systems of signs & codes are intentional. According to Brian Smith, how we represent objects of the world and real-world situation in the computer is the vital point in understanding human functioning. So he says that experience we have with constructing computational (intentional) systems may open a window onto something to which we would not have any access [7]. Therefore, present research will suggest ways to design and develop systems, which are more suitable for varied situations and users.

Above research work is related to field of Man - Machine Interface (MMI) / Human - Computer Interaction (HCI), HWID in particular with the installation and operation of machines in the power plant. Here design of interfaces and interactions with control panel effect working of human operators. Through better-designed interfaces we can increase effectiveness, safety, and decision-making. Thus understanding the work situations and processes are important for improving design of control room and interfaces. It is important that how we could design machines so that they help human in every aspect and they will be their most efficient and effective assistants.

2.1 Work Study

To study human interaction with environment for studying power plant control room systems we require the understanding of what we mean
by ‘information’ and flow of information within particular situation. Information is experienced in perception, retained by memory, and manipulated via symbols. Thus, ‘information’ is central for the exploration of technical, social, and aesthetic bases of human interaction with the world. This provides the framework for our understanding of the underlying patterns of ‘information’ transmission, storage, and retrieval. Conceptual knowledge of concepts such as ontologies, usability issues, and knowledge management help us to create better systems. Conceptual structures based model assist learner in retrieving, evaluating, and comprehending information through the use of semantic associations. This helps in knowing, how we discover and learn regularities in the environment from the consequences of our actions. How information, communication and technologies (ICT) can best be used for effective and efficient transmission of information to all irrespective of socio-cultural background and abilities? The above analysis is based on some goals and performance measures and their understanding. How interface design can be improved through approaches such as ecological interface design [8]? What are testing methods & situations that show the effectiveness of the interfaces?

Further, this problem is not simply programming but it involves cognition, our spatio-temporal movements, and our awareness of the environment in which we work. Therefore this problem includes representation of the world, processes involved, and comes under multi-disciplinary Cognitive Work Analysis (CWA) and Human Work Interaction Design (HWID) frameworks [6]. The problem requires understanding of the relation between human and machines that we can study in a complex socio-technical system such as control room of power, oil, and gas industries or particularly energy sector. Here our aim is to analyze the whole system not just human operators or machines in isolation but complete work settings so that individuals can act more effectively and preserve system safety and efficiency. We are analyzing work domain of the hydropower plant control room as shown in figure 2.
3 Human System Interfaces based on Ecological Interface Design

To study work environment and particular situation we are using CWA and HWID frameworks and focusing on guidelines related to Human System Interfaces (HSI). Embodied view provides a sharp contrast from the standard information-processing viewpoint, in which cognition is seen as a problem of recovering details of the pre-given outer world [2]. In this light, the mind is no longer seen as passively reflecting the outside world, but rather as an active constructor of its own reality. The mind thereby becomes a distributed entity, an emergent characteristic of the whole sensory-central-motor neural system, existing in the elaborate network of interconnections that extend throughout the body. The philosophy of embodiment also stresses temporal, physical, and socio-cultural-technical situatedness. And, quite significantly, the embodied view in cognitive science allows for direct social and cultural interaction, which is crucial for understanding work situations.

In any power plant control room there are two objectives: first is to present to the operator components of plant and second is to minimize in-
formation or Cognitive overload on operator. To exhibit this, traditional display is shown in figure 2 and ecological display in figure 3 based on ecological interface design (EID) [9]. EID presents intangible abstract concepts visible and meaningful to operators [8]. For analyzing work situations in control room following questions are important:

- Objects representation and their meaning
- What makes us to acquire knowledge about the objects in the world, their specific relations, and properties
- How we extract information, its meaning
- Ontology of objects

---

Fig. 3. A traditional display for the steam system [10]

Fig. 4. An ecological display for the turbine system [10]
Ecological display clearly represents reactor pressure, enthalpy, temperature, pressure, and mass flow balance for better decision making. Through this work in progress, we would like to improve information displays, layout of system information, processes, and alarm system of a complex system such as power plant. Besides this study intend to find link between electricity distribution and control room status. These are larger unit of analysis and involve social-technical and cultural issues.

4 Research Analysis and Discussion

Hutchins tried to show that the cognitive science approach could be, with little modification, applied to a unit of analysis, which is larger than an individual. The unit of analysis here is a larger cognitive socio-technical system, such as an automated industrial setting (electricity distribution system [11], [12] power plant control room) [10], [13] and airline cockpit [14]. This approach is related to cognitive work analysis of studying processes in work environment. In both approaches, the question remains the same: what are the structures and processing of representations, which are internal to the system? To explain information-processing properties of individuals or larger systems, it is difficult to infer what is inside their mind [15] [16]. But for larger socio-technical systems, it is possible to directly observe the different representations that are inside the system, despite being outside the brain of individual. The above objectives can be attained through analyzing the various contributions of the environment in which work activities take place. Such as representational media (e.g. instruments, displays, manuals, navigation charts), the interactions of individuals with each other and their interactive use of artifacts (computer systems). Simultaneously, how information necessary to cooperate is propagated through the system by representational states and across machines is analyzed.

CWA is a work-centered conceptual framework developed by Rasmussen, Pejtersen, and Goodstein. Through CWA designing of constraints based interfaces is possible and such interfaces support operators in dealing with uncertain events and proved to be useful not just usable interfaces [17]. Through CWA & HWID we analyzes the work people do, the tasks they perform, the decisions they make, their information
behavior, and the context in which they perform their work [18]. CWA is a holistic approach and examines several dimensions: the environmental, organizational, social, activity, and individual. Therefore, we require a multi-disciplinary approach to apply concepts of CWA to study complex system [5].

In present research, we apply HWID framework for power plant control room panel interfaces to design the information system interaction and activities. As we live in the world, environment and interaction with others plays an important role. Thus both the paradigms find applications in various research projects and areas notably are studies of work domain analysis, robotics, autonomous agents, and interactive interfaces. These research directions will also be central for future developments of man-machine interaction, studying and enhancing the limits of information processing capacities of human and machine. These understandings result in better cooperation between human and computer that will enhance our capacities as supported by technology. Present research work explores the complex work environment to study cognition, cognitive tasks, and mental representations that will result in computational model of control room interactions and work setting for information handling based on CWA [19] & HWID (as in fig. 5). Further application is using Abstraction Hierarchy method for the redesigning of the Control System Man-Machine Interface (MMI) of the Medium Tension Distribution Network of the Public Power Corporation of Greece [20].

![Fig. 5. Framework for Work – Activity Measure Analysis](image-url)
5 Conclusion

This research provides understanding of cognition underlying human interactions with machines to improve design of both machines and work situations. We need interfaces and work situation, which reduces error and cognitive overload on human. Thus use of cognitive system engineering in the energy sector will helps us to analyze, model, design and evaluate effective human integration in complex socio-technical systems. The role of human operators in power plant control rooms is not only to control plant but also to meet market conditions and goals. With the advent of new Information Technology infrastructure we need to assess information requirements to manage control room that suits both human, machines, and economies.

Natural Interactions: An application for Gestural Hands Recognition

Arminda Guerra Lopes
Instituto Politécnico de Castelo Branco
Escola Superior de Tecnologia
Portugal
aglopes@ipcb.pt

Abstract. This paper presents a system proposal for the development of new human-machine interfaces focused on static gestures recognition of human hands. The proposed methodology relies on the use of simple computational processes and low-cost hardware. Its development involves a comprehensive approach to the problems of computer vision, based on the steps of the video image capture, image segmentation, feature extraction, pattern recognition, trained and interpretation of results. The importance of this work relates to the need to build new models of interaction that allow, in a natural and intuitive way, the communication of people with machines.

Keywords: Human-Computer Interaction, gesture recognition, computer vision, image processing

1 Introduction

When communicating in presence, we make it through the speech and with corporal expressions that are complementary. The speech awakes the hearing sensations and the corporal expression seats in visual incentives.

When we intend to transpose the way of communicating, natural to Man, as way of communicating with the machine, several difficulties occur. Nowadays, the Man had to produce several interaction devices with the machine, as the keyboard and the mouse, but none in such intuitive way that is considered natural (to the own Man). On the other hand, we know that some people do not have the ability to handle those devices, but they possess the enough ability to interact with a system of recognition of gestures [1].

It becomes evident the need to build models of Human–computer interaction through gestures that allow, in a natural and intuitive way, these people's communication with the machines.

With the evolution of the image acquisition technologies and image processing, it is possible to build a system that able computers understand the sign language. This is a consensual subject of great importance to computer vision researchers.
However, the construction of this kind of system presupposes the use of highly complex algorithms.

Different types of algorithms for gesture recognition are being studied, but the challenge lies in the fact that this interaction becomes independent of devices that assist the identification of the human hand, such as gloves or sensors for motion capture.

We verified that the development of algorithms for identifying gestures, based on low-cost video cameras, is a great incentive to Computer Vision.

This work’s main objective is the development of a system for static gesture recognition with one hand only, located in front of a webcam, in a simple and uniform background scenario, without the support of assistive materials and implemented in the C++ programming language with the aid of OpenCV library.

2 Technology

Recent technological advances in hardware, particularly in video games, have allowed the development of alternative interactions.

The Microsoft Kinect sensor combines a camera for faces and gesture recognition, depth sensors that allow identifying the depth range of the objects, and microphones that are able to isolate the user’s voice of other sounds. It can transmit the image stream, the depth flow and audio stream that are interesting information to work.

Regarding software, we also noticed a trend, as there are already some libraries devoted entirely to this subject.

The YVision platform includes a set of programming libraries developed for prototyping multimedia applications [2]. It allows the development of complex systems using pre-built modules, controlled by behavior trees. This architecture is well accepted by the gaming industry, widely used in the development of complex final multimedia products.

The OpenCV library is multi-platform, free and open source set of tools for Computer Vision and Image Processing algorithms implementation in real time [3].

3 Gestures

There are many definitions and debates about the definition of gesture. Pavlovic [4] presents a definition of hand gesture that combines the development of posture and position in time, with the intention to communicate or manipulate.

As part of Human–computer interaction, gestures imply the use of the hands to instruct a machine and its meaning depends on the system that integrates and evaluates them. Point or rotate actions are representative actions of this type of gestures.

We can differentiate the gestures in two types: dynamic and static.

The dynamic gestures necessarily involve time evolution [5] and require movement to transmit the intended message. The gesture to say "goodbye" is an example of a dynamic gesture performed with an open hand and is only meaningful if done with movement.
Furthermore, static gestures do not include movement to transmit the message. The same static open hand, with no motion made, forward the information to "stop".

In Computer Vision, we can state that static gesture is a configuration of the hand pose represented as a single image. A dynamic gesture implies movement, represented by a sequence of images.

However, in this work, we will limit ourselves to the static symbolic gestures performed by one hand.

### 3.1 Static Gesture Recognition

Knowing that static gesture is represented by an image, the recognition is based on feature extraction discriminants of the image. We can, for instance, to extract features as the directions of the fingers or the contours of the hand.

The position of the palm of the hand and of the fingers has been widely used for gesture recognition [6], [7].

We can also treat other information about the hands as the angles [8], roughness [9] or sampling points on the boundary region of the hand [10], [11].

Another category of resources abundantly used implies the notion of moment. It is a weighted average of the pixels intensities of an image, usually chosen to have some interpretation. We can find statistical moments [12], Zernike moments [13] and Hu moments [14] they used the most.

Fourier analysis can also be applied for representing the limits of the hand [15].

The feature extraction is a complex computational problem because it requires perfect background characteristics and high computational resources. Disorganized background images with changes in lighting conditions become very difficult to handle.

Allied to this, the used algorithms require loading the whole image into memory, which complicates the management of the computer resources.

After extracting the features, then we can classify the gestures. The more simplistic way of static hand recognition is to count the number of fingers [7].

Nevertheless, recognition can be seen as a matching process, applying cluster algorithms [15], [16]. In this case, recognition consists of find the best match between images that represent static gestures. We may also do the same correspondence with Chamfer distance algorithm [17].

In addition, the Neural Networks are widely used in the hand postures detection and classification [18], using two or three layers of neurons.

More recently, techniques of face detection have been applied to this problem. The Viola and Jones system that leverages the features Haar [19] is a consensus for subject researchers.

### 4 Methodology

Based on [20], the proposed method for symbolic gesture recognition follows a
logical and complementary tasks sequence in terms of digital image processing.

![Diagram of image processing steps](image)

**Fig. 1.** Fundamental steps for the proposed work

The image acquisition is made by a low cost webcam.

The preprocessing and postprocessing, use image enhancement and noise reduction techniques by analyzing environmental lightning conditions and background colors. This happens due to difficulties in illumination.

The image segmentation obtained by Computer Vision algorithms, allows the separation of full human hand in a simple and uniform background scenario, without benefit of supporting devices.

The features extraction performs only in the frames requested by the user.

The classification step bases on the use of the recognition patterns classifier to train and classify the input data.

## 4.1 Image Acquisition

The process starts with the gesture acquisition by the webcam and presented through video images.

![Captured frame](image)

**Fig. 2. Captured frame**

## 4.2 Segmentation

Segmentation is the main part of the entire process and assumes a sequence of tasks (Fig. 3). This stage makes the human hand recognition by skin color detection.
The procedure starts with the frames conversion captured for the normalized RGB color space, which some authors recognize as advantageous for color segmentation [21]. Knowing that the majority of human skin color tends to cluster in the red channel, we extract this channel (fig. 4).

After that, we subtract the background of the extracted red channel image. Background subtraction allows us to obtain a greyscale image with color intensity changes between the background and the hand, as shown in Fig. 5.
Then, we design the image histogram and compute the optimal thresholding value. To do this, we used the Method of the Valley that consists in checking how many regions there are (peaks and valleys) in the histogram and use the valley information to set the value of the threshold. Fig. 6 shows the histogram and optimal threshold value identified.

![Image Histogram with optimum threshold identified](image)

Finally, we use the found threshold value to binarize the image (fig. 7).

![Binary image](image)

**4.3 Feature extraction**

The feature extraction allows obtaining a set of vectors of features, also called descriptors that can distinguish accurately each object. The first thing to do is to normalize the image size. To do this, we define a region of interest (b), and scale it to the image size. Fig. 8 clarifies the process.
After that, we convert the image data into an array of features and associate them to a class. Pattern recognition involves the representation of extracted features in continuous, ranges or discrete values.

### 4.4 Classification

The underlying concept to object classification is quite simple and derives on k-Nearest Neighbor (k-NN) algorithm. This method determines the class where a given object belongs by the majority of votes of its neighbors, and is associated to the class with more similarities among its closest neighbors [22].

![Sequence of classification steps](image)

In pattern recognition, the system requires a prior training to be able to sort the elements. First, it is necessary to define the amount of classes and the respective samples of each class. Later, with this information, we train the system. It follows the model test to gauge the error measurement resulting from the training. Then, we are ready to classify the input image.
Applications

The recent emphasis given to symbolic gestures based applications relates to its potential use in human-machine interfaces. The gestures can naturally increase the interaction between the user and the computer, replacing devices such as the mouse, keyboard, joystick or buttons in machines control. However, a great incitement for gestural interfaces development comes from the growth of applications for virtual environments [23], such as surgery simulation.

In the majority of these applications, the gestures are seen as triggers to virtual objects control, simulating the 2D, 3D or abstractions of real objects, such as robotic arms.

However, not all of gestures applications are designed with the goal to manipulate objects. It has use in message transmission. The practice in communication through sign language or teleconferences provides this type of opportunities [4].

We could outline other gesture interface applications as the development of forensic identification techniques, young children computer interaction, emotional states of patients monitoring or remote control television [24].

There is a vast potential in gesture recognition practice. The mentioned applications are the first steps towards that. The need for development is therefore well clear.
6 Conclusions

It has been shown that it is possible to interact with the computer most naturally and intuitively through hand gestures without requiring support material such as gloves or markers. This work achievements points to the possibility of developing Computer Vision interactive systems based and implemented on conventional computers using inexpensive devices, accessible to all.

Still, we established that the system produces satisfactory results with fixed constant lighting conditions, with a white scenario. The method used for skin segmentation exposes some flaws, mainly caused due to lighting variations causing glare, reflections and shadows. These shortcomings are minimized applying morphological filters and smoothing filters.

Therefore, the proposed system proves to be capable of being used in the development of human-machine interfaces in controlled scene conditions.

However, the systems works with quite different hand gestures, but it shows some weakness when using more identical gestures such as sign language.

In future work, the study of methods that may respond better to lighting variations, to different scenarios and how to be more effective in identifying the skin, even from other races would be helpful. The gesture recognition through dynamic movement analysis can also be a target for further investigation.

Thus, the development of applications using human hand gestures recognition could serve as input interface for running computer programs, without the aid of the most common devices such as the mouse or the keyboard.

UCD Guerrilla Tactics: A Strategy for Implementation of UCD in the Swedish Defence

Elina Eriksson1 and Anna Swartling2

1 Media Technology and Interaction Design – MID, KTH - Royal Institute of Technology, SE-100 44 Stockholm, Sweden, elina@kth.se
2 Scania CV AB, SE-151 87 Södertälje, Sweden anna.swartling@scania.com

Abstract. The problem of how to implement user-centred design (UCD) is well established as a research topic within HCI. Yet there are unresolved issues in order for UCD to actually be used in practice. This paper will present a case study within the Swedish Defence, concerning the introduction of UCD. The overarching goal of the research was to bridge the gap between work practices and systems development; focusing the efforts on introducing usability in the procurement process. We concluded early on that we needed to develop and formulate an approach that is probably common in practice but not described or used in research. We call this strategy UCD guerrilla tactics. It is to do the unexpected, to introduce UCD through UCD and to choose change projects pragmatically. Our main target group was future users and procurers of UCD methods. We aimed at introducing UCD to them by demonstrating and involving them in the work through user centred activities. It is also a flexible approach based on continuous evaluation of what is feasible and potentially gives the largest outcome. This paper describes the guerrilla tactics, how it was applied in a case study and factors that should be considered when using it.

Keywords: User-centred design; procurement; usability; organizational change; case study; work practice.

1 Introduction

User-centred design (UCD) is well established within the HCI research field but it is still difficult to make UCD work in practice [1, 2]. There are numerous studies presenting cases where UCD has been used or been introduced in organizations [3-5]. However, there exists no silver bullet, in the sense of a context free and all encompassing way to do the introduction [6]. Several attempts seem to use a subtle approach, like Kujala’s Trojan Horse [7] where the field study method was simplified and the results presented in a familiar form.

UCD is by tradition often included when there is a concrete systems development project [8]. But there are many activities concerning work practices and requirement formulation taking place before the start of a project, which means that UCD
activities might come in too late. There is a need to bridge the gap in the procurement process (sometimes referred to as acquisition) between work practice, organizational development and systems development [9, 10]. However there is a lack of techniques and methods supporting procurers to incorporate UCD and usability into their processes [11, 12].

Furthermore, our focus is not only to include UCD in individual projects but to establish a user-centred attitude within the organization [13] with the aim of changing the overall work processes for procurement and development of IT-systems. But how can that be achieved? If the traditional way of introducing UCD is failing, i.e. introducing it in the formal system development process, might there be another way?

User-centred guerrilla tactics is not a concept commonly used within HCI research, though the term is frequently used in industry to describe how to introduce usability within organizations. There is no clear common definition, more than that it comprises using a subtle approach and sneaking usability into the systems development process. Perhaps the most cited use of the term is Jacob Nielsen’s text where he advocates for gradually introducing usability by “… starting with the bare minimum and gradually progressing to a more refined lifecycle approach” [14].

Based on the second author’s previous research in the Swedish Defence [15] we aimed at developing the early phases of systems development: the procurement process. We developed a strategy, which we call UCD guerrilla tactics. It is a pragmatic approach focusing on what is feasible and potentially gives the largest outcome. This meant for example targeting change projects, key people and being open to unconventional activities. Furthermore, it initiates a change by using user centred methods for introducing UCD, i.e. treating the respondents as both participants and recipients. We did this by involving them in user centred activities but also through demonstrations of how usability methods could be used in the procurement process.

To conclude, the purpose of this paper is to present an approach to implement UCD. We do this by describing our case study within the Swedish Defence. The purpose of this paper is not to describe a detailed work analysis but rather to analyze prerequisites for UCD in general where work analysis is a part of the methodology. This paper does not elaborate on the result in terms of the degree of UCD actually implemented in the organizations. Rather, we reflect on the approach chosen and the consequences thereof.

2 Research settings

The Swedish Defence is a large enterprise comprising several organizations where two of the most prominent are the Swedish Armed Forces (SwAF) and the Swedish Defence Materiel Administration (FMV). SwAF is the authority that carries out international missions, protects the integrity of Swedish borders and supports the society in major crisis. FMV is Sweden’s oldest civil governmental agency and its main task has remained the same over time: to strengthen the operational capability of the defence system by acquiring materiel (i.e. the equipment and supplies of a military
force) in a cost-effective way. In most cases, FMV works as a middleman between the
armed forces and the system developers.

SwAF procures IT systems from FMV, which in turn executes the procurements
through contracts with industry. FMV does not usually do any development on its
own; its responsibility is to initiate and supervise contracts with industry based on the
procurements from SwAF. For this work, FMVs tradition is to employ engineers who
analyse requirements and manage projects. Many formal processes have been defined
and the procedures for handling procurement and systems development are extensive.

The individual units within the armed forces are the end-users of the IT systems;
they inform the people in charge of procurement at SwAF headquarter (HQ) of the
needs that arise during the evaluation and use of the systems. They are also in close
contact with FMV as it evaluates both old and new equipment. Finally, during
implementation FMV often engage them to evaluate the system. The units can also
have direct contact with industry if they experience problems with an existing system
and report them to the companies in charge of maintenance and support.

2.1 Research Method

The case study presented in this paper was conducted at the Swedish Defence from
the autumn of 2009 to the spring of 2011. The procurer of the research project was
FMV. Several other research collaborations with FMV had preceded this project with
the main aim of understanding usability issues in relation to the procurement process
[15]. However the focus of this project was somewhat different. The project manager
at FMV wished that our research should be more aimed at making a change rather
than just reporting the current state. Thus the over-arching aim of the project was to
introduce a higher focus on user-centeredness in the early phases of the requirement
and procurement processes at SwAF.

The empirical material was collected through semi-structured interviews with the
procurer, IS strategists, enterprise architects, development personal in units and
usability experts. We have also collected data through workshops with the same kind
of participants. All respondents were given information about research ethics such as
confidentiality and anonymity. The workshops and the interviews were in all cases
except one audio recorded and transcribed. Furthermore, we have at all times been
using research diaries, in which we have written down thoughts, conversations etc. as
well as more structured field notes when doing participant observations. Moreover we
have reviewed an extensive amount of written documents and presentations from the
organizations. The overall data analysis has been iterative and we have revisited the
material many times during the course of the project.

3 Result: Tactics in Practice

The core aspect of the strategy is to shift focus from the end-users of IT-systems to
the users of the UCD methods or the recipients of the result such as procurers,
strategists, project managers or system developers. Furthermore, it is about using
classic participatory methods. The aim is to design a version of UCD that can work in a specific organization and to achieve that through collaboration with the people affected by the new work practice. Here we will describe how we tried to achieve that.

From the outset we considered action research [16] as a suitable methodology for the project. Albeit in the initial discussions, it became clear that this was not possible due to politics within the defence organizations (the politics and the organizational structures are interesting in this case, see Debriefing and Discussion). However, we decided to work as an action research project anyway, but in a guerrilla fashion and not openly. We had a dual aim of both solving a problem in practice as well as a research problem [17], with the drawback of not being able to collaborate to the extent optimal for an action research project.

At the start of the research project, it was not clear how we were supposed to accomplish the change in work practice that the project strived for. SwAF is a large organization and aiming for changing it in its entirety was not an option. We decided instead to focus on finding on-going developmental projects where we could have an impact. We found a project with the aim to implement enterprise architecture (EA) in the Swedish Defence (see Pilot Project). Since one of the trends within SwAF was modelling methodology and EA, this was considered a way of introducing UCD while the organization was changing its work practice anyway.

We wanted to introduce both classic UCD methods as well as new methods that we thought might fit this particular organisation and these particular participants; we chose to explore case study [18], personas [19], scenarios [19], conceptual sketching [20], coaching [21], and Cynefin inspired methods [22]. Several other activities were also conducted. For example, we commented on and proofread several relevant documents produced by others. Furthermore, the first author interviewed usability professionals within SwAF and FMV.

Furthermore, in comparison to traditional UCD introduction which in general have a set agenda, we continuously reflected on how we could adjust our approach so that we could achieve the largest outcome. When we encountered problems we regrouped and found new activities that we thought could be more feasible.

To conclude, we were working on many different levels with UCD: 1) integration of UCD in new formal structures; 2) using user centred methods when working with the project to define and implement new formal structures (with project members and end-users of the formal structures); 3) using UCD methods with end-users of technical artefacts related to the new formal structures.

3.1 Pilot Project

The pilot project we followed (here named the EA project) was working on future rules for how SwAF should be described, a local EA framework, and a methodology for using architecture within the procurement process.

In the beginning the most central project members were interviewed and we constructed a plan for UCD activities. We also participated in project meetings and analysed existing HCI related work to see if parts could be applied to the EA
Moreover, we did presentations of HCI methodology and a workshop with the aim of conceptualizing what user-centeredness could be and the expectations of the project members. In spending a lot of time at FMV and the EA project, we also took part in many informal meetings such as lunches and coffee breaks. The first author also performed an interview study with one of the end-user groups of the EA methodology: officers working in the early phases of procurement.

Due to politics we were not allowed to use the word “coaching”, but the continuous presence in the EA project led to several informal coaching situations, where we were asked to explain issues concerning usability or come with suggestions for further work. At one point the EA project were writing a RFI (Request for Information), a pre-acquisition document and we were asked to evaluate it. This led to usability requirements (both in terms of functional requirements and requirements for a user-centred developmental process) were added into the document.

At the very end of the research initiative, the EA project was given new directions aiming primarily to formulate a change plan for SwAF as well as deliver a prototype of a technical portal, a system for accessing and working with the architecture framework. It was decided that we were to make personas, scenarios of future work and conceptual sketches of the prototype. However this work was carried out separately from the EA project due to time constraints as well as internal political reasons. The work with the personas are described in [23].

Unfortunately the EA project was terminated prematurely by SwAF, and the potential for an introduction was lost.

### 3.2 Terminology

Within the Swedish Defence several terms were used that relates to usability and usability work, some examples are Human Factors (HF), Human-Computer Interaction (HCI), and Human-Machine Interaction (HMI). The usage of this terminology was not clear, as in this quote from one of the respondents: “We usually say Human Factors, and I don’t know if people honestly know what it means, or if people just pretend that they do. [...] We use it and people nod and smile but perhaps they just don’t understand what we do.” Furthermore, in the previous studies of the Swedish Defence [15], the second author had observed that the meaning many respondents gave usability differed from the one the HCI community gives. Therefore, we decided to start using a somewhat new terminology in this research project, primarily Human-centeredness (HC).

### 4 Debriefing and Discussion

We will here reflect on our application of the UCD guerrilla tactics in relation to the empirical data. By analyzing and describing the barriers it is possible to get a deeper understanding of the problems and the potentials of this strategy but also the introduction of UCD in general.
4.1 Usability Competence

FMV had a declining number of usability professionals in the years preceding this research project, with a maximum of ten usability professionals among its 1500 employees. There were also a non-active network of people interested in, and working with usability issues. Since the usability professionals were few they could not participate in many projects and had little time for policy creation or strategic usability work. At SwAF there was a great lack of usability professionals and usability competence. In many of our interviews, with stakeholders from both SwAF and FMV, the responsibility for including usability in procurement was put on SwAF but it was also acknowledged that there is nobody there to take on this responsibility. There were some that had training in systems theory where Human Factors had been a part, but according to our respondents they were scarce and dispersed and mainly working with other things.

The lack of usability professionals had serious implications for the introduction of UCD, as we had no one to collaborate with. Research show that usability practitioners are important [24], not only for collaboration, but also for ensuring a sustainable change in the organization. Someone have to continue to work with these issues after the research project has ended.

4.2 Changing Context

Respondents claimed that the organizations were “tired of change”. One reason being a career related issue: within the Swedish Defence people were encouraged to change positions every three years which in fact had lead to a situation where people changed position as often as every one and a half year. Every time a new person came into higher management they wanted to make their own impression and therefore instigated more or less advanced organizational changes. Another reason was reorganizations due to political reasons [25]. One respondent at FMV put it quite harshly like this: “[SwAF] does not have the energy to develop themselves, [they take the] easy [way out] to handle more acute short term things without methodology.”

Yet another factor related to change was “falling out of grace”. During our research project we saw several projects, concepts or terms that all of a sudden became taboo. For us in particular, two terms came to be perceived as negative: coaching and action research. In line with our guerrilla tactics we found workarounds for this, where we actually tried to use both coaching and action research without using these words. Several of our respondents seemed to be used to the situation, as shown in the following quote: “We put up the sign that is politically correct for the moment.”

The changing context was both a possibility and a hindrance for introducing UCD. There were several on-going change projects where usability and user-centred issues could be addressed. However, the same changing context also put a strain on all the involved personnel, leading to a disinterest in yet another thing to learn and incorporate in their everyday work practice.
4.3 Organizational Structures and Politics

The division of responsibility was sharply divided between the defence organizations; regulated by formal documents from the government and by historical aspects. SwAF is the only authority in Sweden engaged in armed combat, but they were not allowed to perform any kind of development of artefacts supporting combat. The situation was similar for FMV. In general, they were not supposed to develop any artefacts for combat themselves; instead they acted as a support organization for SwAF directing procurements to industry. The interaction between the organizations were settled in collaboration contracts, but also deduced to routines and established practice. Several of our respondents expressed that working with user involvement was difficult for several reasons. One was the distance between users and the development project. When involving users, it was FMV who formally requested resources from HQ. It was not possible for the units or HQ to demand user involvement in a development project. Instead, if they wished that end-users should be involved they had to ask FMV to include it in their offer to SwAF. Sometimes FMV requested user groups and user representatives but never more elaborate and efficient ways of UCD. In some cases, different stakeholders bypassed the routines and through personal contacts made sure that end-users were included in development projects or that personnel from FMV were included in the early requirements process.

SwAF was a very hierarchical organization. For example, the EA project was explicitly told not to contact people working at HQ or in the units. Politics was always present during the research project. At one time, after most project members had been asked to leave from a meeting with the procurer of the EA project, one respondent explained: “This is about P-O-W-E-R.”

Our research interest was to bridge the gap between work practice and systems development within the Swedish Defence. Our starting point was in FMV within a research project. This made sense in some regard, since FMV did work with development and procurement of materiel and there existed at least some usability professionals. However, in order to introduce a higher focus on usability in the earliest phases of systems development much of our attention should be directed at SwAF. With all the organizational and political hindrances mentioned above, this was perhaps not the best starting point for this project. Not all research projects start off in the right situation, e.g. [24]. It is difficult to see what would have been better with an enterprise as big as the Swedish Defence. For us, there was unfortunately no other choice at this point in time. As a result, we had to work pragmatically with the possibilities given, which was part of our guerrilla tactics.

4.4 Terminology

As described above, we explicitly decided to stop using “user centred” in favour of “human centred”. We could immediately observe that this label generated more relevant discussions within the organizations. It also resulted in the integration of human centeredness in the procurer’s project directive for the EA project.
4.5 Following a Project

One of our tactics in this research project was to follow an existing project in order to promote our ideas and change the practice. There were several advantages to this; for example, one gets an organizational context to work in. However we also got associated with this particular project, and when it fell out of grace it was reflected on our work. Furthermore in our case we had to balance the needs from the EA project with the demands from the research project. The deliverables in the two projects did not always overlap, and financially the research project had precedence. Another problem with following a project closely is the detachment needed when doing research. Responsibility concerning for example confidentiality and anonymity did not always match the interests of the project we followed. This is a problem described by Walsham [26]: even though you withhold the names of the respondents there is always a risk that the receiver of the information makes an informed guess. This was accentuated at times when we as researchers got information that would benefit the EA project, but due to research ethics could not be shared with them. To what extent should a researcher act as a go-between in organizational politics?

4.6 Methods

The most successful method we used was the persona method, both in terms of engaging end-users in discussions of future work practice and technology use and as a communication tool with the strategic group planning the future work. The scenarios and conceptual sketches developed were also well received by the strategic group that was planning to develop a prototype.

One interesting event was a breakdown of a workshop held with the strategic group in the beginning of the persona activities. In the workshop we used narratives of the end-users work situation (inspired by the Cynefin framework [22]). From these narratives, the workshop participants were asked to write down characters (someone doing something) and activities (what is getting done) on sticky notes. Then they were asked to relate these to each other, with the focus of understanding the concrete work of the officers in the procurement process. The participants in the workshop protested to the open-ended situation and the language we used in the workshop. We usability researchers, used the words concrete and details in order to direct the participants to describing the actual people doing the work, and the actual work they were doing. The participants, who were all focused on EA and strategic planning, used the same words, but with the meaning of doing more detailed flow charts and UML diagrams on roles and processes which we consider a generalized way of describing work.

We also used the Cynefin method for alternative history [22]. It was used in the beginning of the project in order to gain a better understanding of the participants’ views on UCD and their expectations for the project. Several obstacles for introducing UCD were visualized and in fact, many of them turned out to be problems during the course of the research project.

The least successful method was a traditional case study with interviews followed by a written report of the findings. Even though we could later use the interview data
for the work with personas and scenarios, the recipients did not see any use of the report. This might be related to the dominating way of communicating findings and ideas within SwAF and FMV being presentation slides, which is a less dense format.

### 4.7 Multitudes of Levels

During our research we have been grappling with an elusive meta-level. The supreme goal of our research was that the end-users, the soldiers, should have usable technical artefacts, but we were not working with the development of these artefacts. Our focus was rather the people developing these artefacts and our mission was to develop the work practice and the methods for them: the users of our methods. We were trying to work in a user-centred manner with these users in focus, to make them work more user-centred with their users in focus. This notion is not always easy to convey.

An example of this was a recurring discussion we had with representatives from FMV. They argued that our focus was wrong and wanted us to define what benefit the end-users would get from our research. We tried to explain that the end-users would get a benefit in the end, but that our research result was a step in the right direction rather than contributing to technical artefacts in that particular moment in time.

Many of the activities we did were directed towards getting research data or information for the EA project. But at the same time offering an example for how they could work in a user-centred manner. Difficulties arose when trying to report back to the EA project. What should we emphasise: the results from the UCD activities, i.e. the information the EA project were mostly interested in, or the UCD methods themselves which was something we wanted them to include in their visions for future systems development?

### 5 Conclusion

We have explored a pragmatic reflexive user centred approach to the introduction of UCD, which we call UCD guerrilla tactics. It was used as a way to initiate a change process within a large complex organization by the use of very small resources. More intuitive versions of this strategy are probably applied in industry on a daily basis but it is seldom used (or at least not acknowledged) in research. We wanted to explore it in a structured way in order to analyse its potentials. It is also a contribution to those who focus on HCI research closely related to practice.

A successful outcome of a change project such as this, would be to see changes on both a macro and micro level [27], that is in the organizational culture and the formal documentation and routines, as well as on a level of actual practice. Consequently, this case study was not successful since we did not see any changes on macro level during the project. This was partly due to the EA project being prematurely ended.

Our research has confirmed previous research that it is not enough only with guerrilla or project activities, you need management support and an organization that is involved in the specific activities. But we have also found that the guerrilla approach has effect in the small perspective, a noticeable change in sense making was
observed in the people we worked closely with, i.e. a change on micro level. We therefore argue that UCD guerrilla tactics is a necessary pragmatic contribution. We conclude that a successful implementation of UCD requires three things: 1) explicit widely communicated support in the organization; 2) a local infrastructure with usability competence and well defined UCD methods; 3) guerrilla activities where UCD is tried and exemplified in any opportunity given.

We argue that one important part of guerrilla tactics is adaptability. Due to the rapidly changing environment, it is important to at all times be prepared to change focus or search for new strategies for UCD work, to do the unexpected (in the sense of making pragmatic unconventional choices) in order to survive. In this, a constant reflexive process is needed: continuous evaluation of the situation in order to adapt to the changing situation. Most of all, to be able to come up with new solutions and be prepared to let go of some prestige as we did when we changed our terminology.

Ultimately, when introducing UCD with UCD we have learnt that it is important to not underestimate the difficulties with multitudes of levels: working both with methods and processes on a general level and with the result from using them. We argue that one cannot be too obvious when it comes to these different levels. Would we do the project again, we would be more aware and clearer in our communication with the organization on what we mean by introducing UCD with UCD and we would try to visualize it in a better way.

Acknowledgements. We would like to thank all the respondents and collaborators within the Swedish Defence. A special thanks to Jan Gulliksen and the anonymous reviewers who gave feedback on earlier versions of this paper.

Feedback in a Training Simulator for Crisis Management: Information from a Real Life Exercise

Olga Druzhinina and Ebba Thora Hvannberg
University of Iceland
Dunhagi 5, 107 Reykjavik, Iceland
olgaromanovna86@gmail.com, ebba@hi.is

Abstract. Designing feedback to trainees in a training simulator for complex cognitive domains is demanding but has not been given adequate attention. This paper aims to understand the importance of early work analysis in a real context during the design of such a simulator. More specifically, the aim of this research was to learn whether there were differences between the types of feedback given to the learner in an already planned design and a real life training exercise. Therefore, a comparison between feedback given to trainees in a real-life training exercise and feedback planned for a virtual environment supporting training of crisis management was made. The results showed that there were several significant differences, and a theory which emerged from the data analysis could be useful for designing feedback.

Keywords: Feedback, work analysis, human computer interaction, interaction design, virtual environment, training simulator, crisis management training

1 Introduction

While training for crisis management in the advent or after an airplane crash is vital, it is complex and resource demanding, involving many organisations such as medical, police, rescue, airlines and airport operators[1]. The tasks of operational units involve field work, such as medical aid, transportation of casualties, triage of wounded, etc. It also involves coordination and decision making[1]. Training is carried out regularly in comprehensive life exercises, often involving at least a couple of hundred participants, trainees, instructors and organizers of the exercises. Trainees representing emergency personnel engage in activities where fast situation assessment and reaction are the main tasks[2]. To keep the cost down, while maintaining the level of training requirements, simulators have been developed [3, 4].

Designing such simulators is a difficult task, since crisis management requires not only knowledge domain of managing crises, but also skills that enable workers to respond to unexpected and variable events and situations which neither may have apparent causes or foreseeable consequences to reactions[1]. Another aspect of design of such a simulator is to decide the instructional design. Instructional design is a systematic practice of analysing learning requirements and based on them, designing a
set of instructional specifications [5]. Instructional design models span over the lifecycle of an educational artefact through the stages of planning, designing, developing, implementing and updating where applicable. The instructional design of the crisis management simulator included experiential learning, with variable uncertainty of events and situational complexity [6].

Crisis management involves teamwork in a safety critical domain requiring actors to collaborate and communicate to manage information, make decisions, plan and delegate tasks. Teams are formed at different levels, e.g. there are organizational teams, e.g. fire fighters, medical personnel and police, and there are actors from these organizations which form teams at various posts, e.g. at command centres or at the accident site. In crisis management simulation, the activities of trainees are divided into two main categories: field and command [2]. Field activities are carried out by trainees representing emergency personnel, who aim towards learning to assess and respond to a situation as effectively and quickly as possible. Field activities mainly involve rescue, triaging casualties, providing medical aid, transporting resources and casualties. Command activities involve the command and coordination staff, who is responsible for planning, strategizing, decision making and coordinating on a larger scale [2]. Command activities include organizing resources, e.g. people, transportation, medical aid, hospital resources etc., mitigating risks, assessing situations, responding to them and planning. A wide range of expertise appears during training and operations of crisis management, where responders and commanders include novices to experts [7]. Furthermore, to add to the heterogeneity some are professionals but others are volunteers from search and rescue organizations, Red Cross etc.

Not only is it necessary to design a system which simulates work and situations, but to design a stimulating and rewarding training environment for trainees. Experience has shown that during simulator tenders technical issues are prioritised over functionalities for supporting training [8]. To encourage better practices, Naikar and Sanderson [8] have illustrated how work domain analysis [9] can be extended to define training needs. They have argued that common techniques such as instructional system development (ISD) [10], which has been applied extensively by the air force in military training, is inadequate since they do not support work which is characterised by cognitive work, adaptive behaviour, random events and unpredictable situations.

In addition to identifying training needs, designers of simulators have to decide how to deliver training, that is, which methods to use. Much has been written on professionals’ reflection in action [11] and practitioners’ ability to self-assess or self-monitor [12]. Feedback is one of the most powerful techniques to help students learn. It provides learners with information on their performance when gaining or applying new knowledge and can help them to find the right answers [13, 14]. Feedback can either be intrinsic, available in a normal job situation, or extrinsic, which is available from an instructor either during or after a training exercise [15]. The latter one is also termed explicit feedback [16] which can come from a human tutor, a pedagogical agent, disembodied coach or other intelligent tutor [17].
work to a large extent. Since feedback is one of five components of teamwork [18, 19], it becomes even more prevalent than in single learner situations.

To meet this requirement of learning through feedback, most educational systems need to provide information on the assessment of learning to the trainee in some form [20], whether it is given by the system, or by a person, e.g. either a teacher/instructor or a fellow student. Although a simulator for crisis management training is not a game, we expect that knowledge from that field can be adopted. Researching designs of learning in games, Liu et al. [21] state that assessing the progress of a player’s learning activity is one of the most rewarding interactive behaviour. Such systems should provide appropriate feedback in order to assist the player in the learning experience [22], and it should ensure continuous flow to motivate the player to proceed [23].

Despite the substantial emphasis on including feedback in games or simulators, it seems that its design, or methods for its design, has not been given as much room as required [24]. Recently, there have been examples of methods to provide in-game assessments of objects and actions taken in real time. These assessments correspond to logged, time-stamped events that undergo statistical analyses. Following, they are displayed in real time or during a review occurring after the game [3].

Motivated by this need, the objective of this research is to compare, in terms of feedback, a plan for designing a training simulator to data gathered in a real-life training exercise for responding to an airplane crash. Thus, we hope to learn about the kinds of feedback learners receive and to demonstrate the requisite to include real-life exercise data analysis as a part of the design of a training simulator.

2 Research Methodology

The research method is a work analysis of trainees’ performance during the life exercise of emergency management. The feedback in the life exercise is compared to a system master plan of a virtual environment of a crisis management training simulator using categories from literature. The life exercise train was conducted at an international airport in Europe and included almost 250 participants, with 90 participants creating the training scenario and serving as instructors, and the rest training for crisis management. The main exercise lasted 4-5 hours and included all organizations involved in a regular response to an aircraft incident. Seven participants of the CRISIS project served as observers, taking written notes and photos. The CITE system from VSL was used to enter notes during and after the exercise. In total, 548 observations were made for four hours at five different locations of the exercise: Emergency Operations Center (EOC), Casualty Assembly Point (CAP), Rendezvous Point (RVP), On Scene Command (OSC), and Accident Site. In addition, a few observations were made by instructors of the exercise, who were using the CITE system as a pilot.

Spanning well over 300 pages, the system master plan of the CRISIS training simulator (CRISIS VE) includes a detailed description of the system design and architecture, description of key concepts, such as events, variable uncertainties, and the CRISIS training cycle. Furthermore, it includes reference scenarios and example sce-
narios. Finally, it contains a list of roles for each of the scenarios and extensive lists of functional requirements for different modules and technologies of the simulator. The system master plan is written after a thorough requirements analysis including site visits, interviews, questionnaires and a visit to one real life exercise. Moreover, a contextual design [25] analysis was carried out, but only based on the above data, and not by gathering data in a real context [4].

The classification of the feedback data from the real life exercise and its analysis was carried out independently by two researchers. Each researcher classified data according to different feedback types, which are based on the literature and will be presented in section 3. Afterwards they discussed and merged their results. Altogether there were 49 feedback observations out of 548 observations noted down by observers.

3 Forms of feedback

Feedback is an essential aspect for any learning environment, as it provides assessment of the learner’s progress and results, motivates the learner, and enhances learning [26]. Feedback in any learning environment may be categorized [26]. For example, feedback may be qualitative or quantitative, e.g. “Good”, or “65 points” [27]. Furthermore, feedback may be negative, positive or neutral [24, 28], and it is stated that negative feedback is more helpful to the learner [26]. Also, feedback can be either corrective and/or motivational, where corrective feedback has the purpose to correct the learner, while motivational feedback motivates the learner, based on his/her individual preferences [29].

Feedback may be in a form of elaboration or verification. Verification feedback refers to the notification of the result of the learner’s answer, i.e. simply whether it is correct or not. Elaborative feedback refers to a response that provides an explanation of the result of the learner’s answer, and, in some cases, gives a hint to a solution [30, 31].

In a team, the process of providing feedback is not the same as in single person-to-person communication. As Sonntag [32] points out, in unidirectional teaching environment, where feedback is teacher-to-student and vice versa, feedback is a simple process, while in multidirectional environment (in a team) feedback becomes a more complex process. While Sonntag looks at the integration of aspects within the teaching environment, the issues raised are relevant to the case with a training simulation. Sonntag puts emphasis on how teacher should coordinate students, and organize materials and feedback in a multidirectional environment, in order to pass the right message onto students. The main concern is that students may misinterpret, underestimate or ignore bits of information [32]. In a similar manner, crisis trainees may misinterpret or not respond to information from an operational unit. Or, for example, if a trainee receives contradictory information from two other trainees, s/he may be left confused unable to proceed in such a case. Thus, unlike unidirectional, multidirectional feedback holds a rather arduous character due to the distributed interaction nature of the environment. Therefore, it should be taken into account when designing...
scenarios, that learning how to deal with wicked problems due to multi-directionalism is an important aspect of crisis management training. Unidirectional feedback incidents occur in crisis handling as well, and the two need to be distinguished. 

Above, we have described some types of feedback in the learning context. We now give a few examples of how a software application can provide feedback to a trainee. Feedback in a virtual environment can be categorized according to senses, i.e. visual, haptic, or sound [21, 22, 33]. There are two types of feedback in virtual environments, either immediate (real-time) feedback that can be issued to the player during the game or delayed or archival feedback that is issued as a summary upon completion of a task or a game [26, 34]. Immediate feedback which is automatically generated by an application can be of any form mentioned above, while delayed feedback is usually given in text or graphical, form [21, 24, 26]. For example, action feedback is an immediate interactive response in real-time, while text feedback can be both immediate and delayed [21]. Immediate feedback may be provided during the execution of a task, usually when the task is complex, or after task completion if the task is relatively straightforward [24]. For example, in a car simulator, the player may get immediate haptic feedback in the form of vibration during the execution of a task.

Liu et al. [21] and Kiili [22] state that feedback is accepted more seriously by the player if it is provided immediately, instead of being issued after the game completion in the form of instructional text material. Also, according to Garzotto [35], when an action taken by the player is incorrect, it may be necessary and more effective to provide immediate than delayed feedback, since the player might later forget the incident, and, hence, not learn from delayed feedback. However, Renaud and Cooper [24] argue that archival feedback is also important, and may be presented in the form of text and/or graphically. Where appropriate, graphical feedback is more helpful than text, as it depicts the information as a whole [24]. Furthermore, feedback may be provided as an action replay in the form of a video [24].

4 A Case Study

We decided to use the development of the CRISIS training simulator as a case study to understand how feedback is designed. We have decided to compare the data from real-life exercise to a system master plan of an existing training simulator, because we hoped to find out if there were any major differences between the two approaches to training for crisis management. Real-life training has many drawbacks, e.g. the costs of equipment and organization, and menace to environment [1]. However, it remains unclear whether the level of feedback delivery in a simulation, an essential part of training, may be the same or comparable as in real-life exercise. In the next subsection, we review the master plan for the CRISIS VE training simulator for feedback design aspects. The data from the life exercise were analysed with respect to feedback. In the section on Work analysis feedback instances are discussed.
4.1 An Analysis of a System Master Plan with Respect to Feedback

In this section we describe an analysis which we have carried out on the System Master Plan [2] for the CRISIS VE with the aim to see what requirements have been specified for the feedback to be provided to the trainee. CRISIS VE was designed to support the 4C/ID instructional design model, which is meant to be used for long-period training with multiple complex tasks and learning objectives [30]. The 4C/ID instructional design model focuses on complex learning tasks and comprises four components, a) learning tasks, b) supportive information, c) just-in-time information and d) part-task practice [5].

CRISIS VE supports functions to diagnose and to make a full After Action Review (AAR) of a trainee’s action, decision and behavior based on data collected throughout the simulation game. Thus, the AAR module provides a quantitative summary report of the trainee’s overall performance and details of an exercise. Based on this data, the instructor submits his/her own qualitative comments on the trainee’s performance.

CRISIS VE supports immediate visual and action feedbacks. CRISIS VE supports immediate visual feedback, e.g. when a trainee places a Casualty Assembly Point (CAP) at a location, the system immediately draws a CAP object on the screen. An example of how CRISIS VE supports immediate action feedback is when the system prevents the trainee from placing the CAP in an area too close to the site of an accident, since it would endanger the casualties in case of fire spreading. Thus, the system prevents the trainee from making a mistake, but signals him or her implicitly that an incorrect action has been carried out. Furthermore, CRISIS VE facilitates, by supporting communication with fellow trainees, learning by mistake, which is for trainees, according to Pivec and Dziabenko [36], a primary way to learn, motivating them to keep on trying. Trainees will be able to receive life feedback through communication devices implemented in the simulator, such as radio or mobile phone, from other trainees or instructors. CRISIS VE also supports both unidirectional and multidirectional feedback between all trainees and the instructor.

CRISIS VE does not support sound as a form of feedback. Although CRISIS VE includes sounds to resemble the real-life environment [37], it does not notify the trainee of the success or failure of a task completion. While some research is underway for using haptic equipment, i.e. for sensing heart beats of casualties, the CRISIS VE master plan does not include support for haptic equipment for physical sense feedback.

4.2 Work Analysis

Using the data from the life exercise, this section describes feedback a trainee gives to another trainee or an instructor gives to a trainee or trainees. We have put feedback types, either from the literature or our own, in bold. Quotes from the data are presented in quotes and italics.

All 49 instances of feedback during the live exercise were verbal and qualitative. An AAR was presented to trainees verbally at a meeting after the event, but a written report was planned as is the case in such exercises.
Many feedback instances involved discussions (22 out of 49) and information sharing (42), e.g. during regular status meetings when numbers of casualties were reported. Many instances triggered reasoning (20) and organization (22) among participants of an exercise, e.g. when the commander made decisions and organized the other trainees after having concluded “transport capacity is not enough to transport all red casualties”.

More examples of when feedback initiated a discussion were after an issue had been raised (11). At the EOC it was observed “NECC (National Emergency Coordination Center) has complained about not receiving a passenger list”. Raising an issue, also triggering a discussion, was when at the EOC “The radio/computer operator informs that NECC has been trying to reach EOC. The EOC commander replies she is about to contact them”. Another example which shows feedback in terms of raising an issue, at the EOC: “We need transport capabilities from [City excluded for the sake of anonymity] - there is nothing on this in the database. This is a problem”.

In 2 feedback cases the trainee was learning by mistake, e.g. a trainee learned not to inform patients of the death incidents as they became “upset when hearing about dead patients over a nearby tetra unit”.

Trainees were not rewarded upon the successful completion of a task. Although there were many examples of verification feedback (19), such as when one commander tells the other that they “need better information on weapons”, most instances were of elaborative feedback (29) with an explanation of the error or the problem, such as when “airline operator discusses with Red Cross commander how to send the list” after feedback had been provided on not receiving the list although reportedly it was sent. Many of the feedback during the exercise were of a corrective character (20): “Wounded still on the scene”, and only a few feedback instances were motivational in nature (10): “EOC commander concludes that the transport capacity is not enough to transport all red casualties. She asks Resource manager for more resources”.

During the life exercise, trainees were constantly burdened with various hiccups that persisted along the way, such as the equipment failure or data loss. For example, the “police officer reports a radio problem and asks for assistance for fixing it or replacing”.

Some of the feedback is only unidirectional (13), e.g. in the case of providing an assessment of the situation, at the Rendezvous point: “It took too long time for activating resources from the Rendezvous point to the accident site”, or at the On Scene Command post: “[We] need basic information on the status of the triage immediately in the beginning”. A further example implies negative feedback when commander states “there should be better flow”. Feedback incidents that took place during the status meetings were multidirectional with trainees explaining their current state of work and problems. Most (39) feedback instances were multidirectional, as they involved different trainees trying to solve one task. For example: “EOC commander concludes that the transport capacity is not enough to transport all red casualties. She asks the Resource manager for more resources. The radio operator informs that OSC has not requested resources, only to move existing resources closer”.

124 of 179
28/11/2012
In two cases we noted feedback in the form of explicit teaching. OSC realised that the rescue coordinator had misunderstood the role of the OSC. In response, they attempted to inform the coordinator of the correct procedures:

Commander to Planning: “How is the flow?” - Looking at an overview at the display. Planning to Resources: “Do you want to have the ambulances closer?” Commander says: “Transport coordinator should resolve this” - explains the procedure and role of transport coordinator.

Another example of teaching trainee procedures. A commander at OSC:

“I want to iterate that EOC should organize transport of casualties out of the scene - this is not the responsibility of OSC but an EOC.”

Planning personnel at OSC communicating to EOC:

“You should talk directly to the transport coordinator” - Commander looks at the hierarchy with plans and says that according to the hierarchy, the medical coordinator and the transport coordinator should organize the transport among themselves.

Probing for information was noted as a type of feedback. At the OSC at a start of regular status meetings:

“We don’t have confirmation that the scene has been secured. There they come (i.e. the rescue team) (Looking through the window). How much of rescue teams did he send? Do we have numbers from security coordinator?”

In rare cases (2 out of 49) the feedback was emphasised with gestures, e.g. an instructor is pointing to the scene and stating “ambulances should already be on the scene, but they are not”.

4.3 A Comparison between the Planned design and the Real Life Exercise

In the previous section, we presented how trainees received feedback of different types. In this section, we analyse what it implies in terms of learning, i.e. whether trainee will gain knowledge as a result of this feedback or get the message that training needs to be improved in the future. Thus, we hope to present an initial theory explaining the relationship between feedback and learning during training crisis management. First, for assessment of a situation, a fellow trainee pointed out to the trainee that the situation was deficient, and that in future situations this would need be avoided or improved. Second, for raising an issue or probing for information, the feedback pointed out to the trainee that a problem had arisen that could be solved now but little or no instructions were provided. Third, for explicit teaching, the trainee received instructions and guidance on how to accomplish a goal.

Some of the feedback practices in CRISIS VE contradict with the real life exercise. There are differences in the delayed feedback during the real life exercise and in the training simulator. The archival feedback provided in the crisis simulator is only available in text form, and it is quantitative with the possibility that the instructor may provide qualitative comments on the performance. In the real life exercise, the feedback which is given to the trainees as an aftermath of their performance is qualitative and is presented verbally or as text.

The immediate feedback in the real life exercise is provided by trainees, usually in the form of elaboration, both during the task execution and/or after task completion.
In the training simulator, immediate feedback is provided in the form of action by the system, and can be received through conversing with other players via communication devices. The difference here is that the trainee does not get any immediate automatic feedback in the real world, so if s/he makes a mistake, it will have consequences at the later stage of the training. The system, however, tries to prevent the trainee from making a mistake without explanations, and with no further consequences. For example, in real life if the trainee breaks something, the other trainees will have to continue without it, and maybe use another object instead.

While CRISIS VE supports some learning by mistake function, it does not provide feedback to the trainee on the nature of a mistake. For example, in the case of placing a CAP area too close to the accident site, the simulator simply does not allow for the CAP to be placed. There is no explanation on why the CAP cannot be placed. Thus, the trainee may not be sure whether it is a fault in the software or if the reason is the proximity to the accident site. Although in real life a trainee does not get any messages of the sort, in the training environment s/he may become confused if there is no message or alert generated when something is happening unexpectedly. Cyboran [26] explains that learners do not benefit when the system does not specify its response towards learner’s action, particularly when the nature of response may not be clear or obvious. It was unclear from the system master plan if incorrect actions or mistakes were logged for the AAR report.

Furthermore, the work analysis revealed that in real life many feedback incidents are connected to unexpectedness of situations, particularly the equipment failure. However, in the master plan for the CRISIS simulator, there are only some vague suggestions of unexpected incidents.

While the master plan has a general design of feedback and unexpected situations, the training exercise showed that in real life there are several typical situations that would need specifically designed feedback.

5 Discussion

The work analysis has revealed that during the life exercise similar feedback incidents, typical of crisis management training, occurred. Such similar feedback incidents have been classified and grouped, and can be used in the design of a simulator for crisis management training. In preparation for the real life exercise, exercise organisers said they were not expecting a lot of feedback given to trainees by instructors. The analysis reported in this paper showed that although not extensive, feedback was more apparent than expected. In future studies, it would be interesting to contrast this result to trainees’ reflection on their own work [11] as professionals or in an after action review and see how trainees expertise might determine this reflection vs. feedback.

For this research, we have gathered empirical data to show how work analysis can incorporate and shape the design of the feedback incidents through comparison of the work analysis and an earlier design plan. In comparison, Narciss and Huth [30] carried out research, based on literature, to derive guidelines on how to design feedback.
incidents. In their research, they emphasise how the cognitive task analysis plays a crucial part in the design of feedback.

Narciss and Huth [30] proposed three facets of feedback, functions of feedback (cognitive, meta-cognitive or motivational), contents of feedback (evaluative or informative towards the knowledge of the result) and presentation of feedback contents (timing, schedule, adaptivity). Based on this framework, procedures are detailed on how to design feedback. Instruction contexts, such as objectives, tasks and errors contributed to the contents of feedback; and individual factors such as learning objectives, prior knowledge and skills and academic motivation contributed to functions of feedback. Narciss and Huth [30] viewed the contents of feedback in terms of evaluative and informative components. Comparing their classification to our theory the assessment of a situation and raising an issue or probing for information may be considered as evaluative components, while explicit teaching falls in the category of an informative component.

According to Gredler [38], simulations may be of two types: symbolic or experiential. Symbolic simulation presents tasks where a participant must often use or improve theoretical knowledge to solve a problem, e.g. business manager, physician, or mathematician. Experiential simulation presents tasks where a participant is trained to gain knowledge of how to operate a device or perform a set of routine tasks, which require little to no need for scientific concepts or theorems [38]. Since Narciss and Huth studied learning environments for a symbolic type of simulator where trainees solve problems by presenting knowledge of the result, such as subtraction, we do not know if their findings can be directly translated to crisis management training, which is an experiential simulator. Nonetheless, it can be valuable to compare the two types to see how well the design guidelines can be translated from one type of learning environment to another.

The presentation facet should also be taken into consideration when designing feedback for the CRISIS VE training simulator, as it is strongly linked to the development of a natural learning environment, which has been often discussed as one of the main goals in the System Master Plan for CRISIS VE. Since the System Master Plan was focused on describing the presentation of feedback, further research would have to be done on the presentation design issues to analyse the adaptivity and frequency of feedback in the training simulators [26, 30].

The research has some limitations. One limitation was that the observers may not have reported all of the incidents that occurred. Although the data set that we analysed was large, it was only from one live exercise. Thus, the feedback incidents retrieved are specific to that particular training scenario.

6 Conclusion

By comparing data from a real life training exercise to data from a system master plan we have shown that it is necessary to pay more attention to learning aspects of a simulator, such as feedback. Since the comparison revealed significant differences between the system master plan and the real life exercise, the research has shown that
while it is vital to carry out analysis of the domain tasks, roles and scenarios, the de-
velopment of a learning system needs to take into account what types of feedback are
provided in a real-life situation.

Previous research on feedback seems to be scattered in individual areas ranging
from communication to learning sciences, onwards to system related areas such as
HCI, educational technologies and learning games. Moreover, the theory of feedback
in the context of HCI is weak [28]. Furthermore, what makes it difficult is that feed-
back is of varying abstractions along different dimensions, ranging from low lexical
level to a high semantic level, from a drill type of training to training more cognitive
complex tasks in disperse application domains, ranging from Sports training [39] to
Medical training [40] onwards to Pilot training [15].

Accounting for Intermediate Parties in Experience-driven product design for Business-to-Business Environment

Vladimir Abramov, Virpi Roto
Aalto University, School of Arts, Design, and Architecture, Department of Design
Hämeentie 135 C, Helsinki, Finland
vladimir.abramov@aalto.fi; virpi.roto@aalto.fi

Abstract. Experience-driven design has raised interest in development of consumer products, but has rarely been studied in context of workplace systems. In this paper, we discuss some differences that these two contexts introduce to experience-driven design, such as the number of intermediate parties between the manufacturer and the end-user. First, we introduce a simple model, which takes into account experiences of intermediate and end-user parties in industrial product development. Second, we report a questionnaire study of 57 experienced equipment distributors to understand their views on the role of user experience in forklift truck design. Results of the questionnaire study indicate that distributors are able to appreciate differences in hedonic qualities of industrial equipment and that visual appearance is a major factor in indicated product perceptions. However, overall hedonic qualities were perceived as less important compared to utilitarian and pragmatic qualities. We also found that distributors did not appreciate the three major psychological needs (relatedness, autonomy and competence) in the design of a forklift.

Keywords: Experience design, user experience, UX target, industrial context

Introduction

As the nature of products, operations and transactions in business-to-business (B2B) environment has many differences compared to business-to-consumer (B2C) environment, also assessments of product related experiences in these environments are rather different. For example, if it can be shown that positive experiences evoked by some industrial product result in reduced number of absences, sick-hours and increased end-user stimulation and productivity, the customer party will be probably willing to consider paying a higher price for such products. One of the most obvious specifics of B2B environment and industrial products is related to the separation of ownership and actual use of the product. But what are the potential consequences of this separation regarding user experience (UX) in product design?

In B2B context, the key question might be put as whether UX based design approach in product development can be formulated in a way that would provide a better and more robust link between positive experiences of end-users and economic benefits to distributors and customers. This is a relevant question because it tries to
account for challenges associated with the lack of actual product use and interaction by individuals from customer and distributor parties. In other words, customers are often unable to assimilate themselves with product users and appreciate their experiences. In this respect, there are many challenges with various aspects including the time needed to acquire long-term experiences from the product use, understanding needs of users and potential economic benefit from fulfilling them, getting rid of myopic decisions and deriving a holistic picture of how the product fits into overall company image and brand. It can be argued that improved user experience in industrial products benefits the customer and distributor parties whether it is realized by them or not. From this point of view, manufacturers should make an effort to make this realization more visible and measurable for their customers and distributor partners. In addition, B2B setting creates a wholly new set of challenges for user experience approach in product development. For example, one implication for end-users can be seen in reduced or no feeling of ownership associated with the industrial product. This in turn leads to increased barrier for attachment or expression of care in respect to this product. One potential solution for corresponding challenges might be derived from customization and personalization qualities of industrial equipment. In their article, MUGGE, et al. (2009), show how personalized products can elicit emotional bonding and thus contribute to the sense of attachment. Also SCHIFFERSTEIN, et al. (2008), elaborate on possible design strategies which might enhance feeling of attachment and care for products. Trying to improve feeling of attachment does not aim solely at benefiting end-users but is also reflected in advantages for customer and distributor parties. For instance, the result of eliciting feeling of attachment could be seen in prolonged life-cycle of products which are treated with care and repaired instead of being discarded or substituted by replacements. In addition, industrial products that are able to stimulate users can be associated with improved productivity and efficiency. However, individuals who are in charge of acquiring new equipment for their facilities, such as factories or warehouses, are concerned with product qualities and features but often view these qualities from purely utilitarian perspectives such as return on investment point of view.

From the viewpoint of UX based design approach, one of the key challenges is related to “it is just a tool” or similar kind of mentality. It was already pointed out, that lack of ownership can reduce the tendency to become attached to industrial products. Individual product qualities alone are not necessarily enough to shift this strictly pragmatic mindset and somehow automatically elicit positive emotions. One possible way for approaching individuals’ attitudes might rest in trying to shift their motivation from purely extrinsic (e.g. monetary rewards) towards intrinsic motivation (e.g. fulfillment of psychological needs). For example, if some product related activities are undertaken with pragmatic, utilitarian and purely functional attitude (e.g. “I need to attain to this activity because it is part of my work for which I am paid for”), there is hardly room for noticing hedonic aspects of the product use even though all the necessary experiential product qualities would be in place. On the other hand, a person might well attain to a certain work tasks that bring him simultaneously joy and monetary rewards directly or indirectly. An interesting question lies in how the working environment (in a broad sense) influences work attitudes and what is the impact of
individual product features. For example, one way to combine influences of the working environment and product qualities is linked to enhancing salience of individuals’ goals and targets at work as well as providing concrete milestones and paths to attain to these goals. A negative side effect of such practices is related to completion driven working attitude, which results in a tendency to downgrade intermediate positive emotions and experiences in an anticipation of some greater end rewards. The responsibility for creating appropriate working environments and incentives, enabling sufficient training and work practices as well as integrating new equipment into existing systems often falls to intermediate parties such as customers and partially also equipment distributors.

Intermediate parties’ influence on experience-driven design

A direct sale to the customer is not the most typical channel through which industrial products find their way to end-users. Usually there are many other intermediate parties which acquire and distribute these products. These parties might include various distributor, dealer, wholesaler or retailer chains, which ensure that manufacturers can save in distribution costs and customers are able to get desired products close to their location. Although there are undeniable benefits from having various intermediate actors in the distribution chain, this situation poses another set of complications from the perspective of conveying UX in the industrial environment. For instance, if the ownership and product use division between customers (individuals who make the purchase decision) and end-users (typically employees using the product) creates challenges associated with justifying UX to customers, product ownership status of retailers is usually merely temporary leaving rental business as an exception. This setting is somewhat puzzling in the view of defining clear benefits from experience based product design to distributors. One potential advantage might be seen in being able to sell the product with less effort if the message from distributors carries a clear economic benefit trait from better UX to the customer. However, in practice, this is doubtfully a realistic and robust prospect because it inclines that the intended message does not get distorted at any stage from the R&D and sales departments to the retailer party. One idea, which became apparent from interviews with industry practitioners from one of our research partner companies, indicated a possibility to communicate the experience design approach benefits directly to the customer surpassing distributor chains. This could be made possible through the use of IT technology, virtual communities and other social media. It was pointed out by several interviewed individuals that customers become aware of new industrial products via multiple channels instead of relying heavily on the message carried out by distributors or retailers. For instance, customers might utilize their peers to evaluate and share experiences related to required industrial equipment. This direction opens a wholly new perspective on how customers receive product information as well as a potential for the experience-driven design to be communicated with less interferences. On the other hand, if distributors act as agents in rental business, they might benefit from the same positive UX effects e.g. in terms of prolonging the life-span of their rentable industrial equip-
ment as a result of product attachment elicited by end-users. No matter whether intermediate parties such as distributors and customers play a major or a less substantial part in influencing what industrial products are acquired for the company, their perspective should be taken into account already in the very beginning of product development projects. One way to do this is to set customer experience (CX) targets alongside user experience targets to derive criteria for new product qualities.

**Setting UX and CX targets for industrial product development**

The basis for experience-driven design is a specific UX goal (DESMET and SCHIFFERSTEIN, 2011; HASSENZAHL, 2010), also known as experience target. Experience targets can be derived from basic psychological human needs such as relatedness, autonomy, competence etc. (e.g. SHELDON, et al., 2001; HASSENZAHL, et al., 2010). These needs reflect rather abstract and higher level goals which could be set by individuals (Be-goals). Again, these can be subdivided into more concrete actions and activities (Do-goals) as well as corresponding product qualities (HASSENZAHL, M., 2003). Although such hierarchical structures might fall subject to varying interpretations, they are useful in the view of creating basis for common understanding when breaking abstract experience targets into specific desired emotional responses from product qualities. Introduced model in **Figure 1** has three levels of experience hierarchy for customers (from the bottom) and users (from the top) separately. The idea of having these two distinct parties in the same setting lies in simultaneous processing of user and customer needs and following product quality choices. The first hierarchy level can be considered as a starting point for determining UX and CX targets for product development. For example, one UX target could be derived from the need of security and can be broken down into several components, e.g., safe from threats and uncertainties. This abstract notion can be formulated further, for example, as a feeling of safe product operation or a sense of being able to follow product performance. The next hierarchy level considers more concrete activities and product qualities which are assumed to contribute to selected UX and CX targets. For instance, such activity as “following own work progress and selecting new tasks based on their difficulty” can be considered as potentially contributing to a predetermined UX target of competence. On the other hand, an activity contributing to the CX target of security can be seen in “following reports on equipment performance and work progress”. These activities can be linked even further to particular product qualities e.g. “the integrated software must have easily accessible work progress feature” and “the product must include necessary sensors to capture appropriate measures indicating work progress”. At the component level the hierarchy chain ends with possible options for concrete product details and qualities to be tested and later embedded in the final product. When the abovementioned breaking down process is done simultaneously from perspectives of customers and users, it should lead to some set of product qualities that have the potential to satisfy both customer and user needs by meeting corresponding UX and CX targets. However, to get some reassurance that presumed links between experience targets and products qualities are actually possible in the real-life situa-
tions, these links between different levels of hierarchy must be confirmed by means of user and customer research already in early stages of the product development process.

Perhaps one of the main intended uses for the presented simple model is its potential to be utilized as working canvas for ideation and generation of experience driven product development criteria within R&D departments of industrial companies. In this sense, individuals working in product development can take a more holistic view on Experience-driven design accounting also for factors associated with resource allocations, communication channels and material formats required for satisfying both users and intermediate parties. Another useful aspect of the model might be seen in its potential to be utilized for generating UX argumentation chains for marketing and sales purposes. These argumentation chains might be derived from the model when linking UX targets to respective CX targets through concrete product qualities. For instance, one argumentation chain might include consequential stream such as: “Feeling of trust in the equipment among users due to more stable product platform leads to less mistakes in operations. This on the other hand leads to reduced costs from spoiled products and more predictable output. As a consequence, customers feel more reassured about realization of their production plans”. Although this example is overly straightforward and requires a rather robust empirical study to support it, such principles can
be applied to generate more elaborate and catchy consequential streams for selling point implications with experience-driven design in mind.

The abovementioned UX and CX target model tries to highlight that experience based design approach in B2B environment must take into consideration potential product experiences of several relevant parties and not only end-users. In this respect, it makes sense to investigate product preferences of customers and distributors to determine how individuals from these groups perceive needs of end-users of industrial equipment.

**An example from product perceptions of equipment distributors**

The main data set used for the presented example study was collected during two separate distributor events held in April 2012. One of the events was held in Malaga, Spain and the other was held in Vantaa, Finland. All of the 57 individuals included in this core subject group were distributors of forklift equipment on a managerial level. Summary statistics for this subject group are presented in Table 1. The study for this group contained a questionnaire set, which included questions on product quality perceptions, assessments of importance of psychological needs for industrial product development and an AttrakDiff questionnaire. All of the questionnaire sets were provided in printed format and distributed/collected during these two events. Individuals from the first event (Spain) evaluated one product (A counterbalance truck) whereas individuals from the second event (Finland) evaluated two products (A counterbalance truck and a reach truck shown in Appendix 1).

When considering the importance of different psychological human needs to be taken into account in warehouse equipment development, individuals from the distributor party had to indicate their perceptions of importance separately for customers (Buyers of the product) and for operators (end-users). Results of these importance
estimates are shown in Appendix 2. These results show that importance of “feeling of controlled and safe operations”, “feeling of belonging to a community”, “stimulation and pleasure at work” and “feeling of being physically fit and healthy” were perceived as more important for operators of the equipment than for customers and these differences are statistically significant (Wilcoxon signed-rank test). At the same time, none of the presented human needs was seen as more important to customers with statistically significant difference. This finding supports an assumption that human needs in product development would be perceived by distributors as less important for customers because the link from positive operator experiences to improved economic factors is less apparent and hard to measure. Distributors’ perceptions of operators’ needs show that “feeling of controlled and safe operations”, “stimulation and pleasure at work” and “feeling of being physically fit and healthy” are seen as most important ones from the point of view of warehouse equipment development. On the other hand, distributors perceived “trust in technology” and “feeling of controlled and safe operations” as most important needs to account for in equipment development for the customer party. Although presented need perceptions are collected from the intermediate party which is not directly involved in final product utilization, these indications could become relevant when determining CX targets to be emphasized when dealing with this party. In addition, UX targets derived from psychological needs of relatedness (belonging to a community), competence (accomplishing challenging tasks) and autonomy (being able to organize own work) were perceived as less important for product development despite findings from earlier studies (e.g. SHELDON, et al., 2001) showing that these needs are among the most salient ones for individuals. This indication calls for further investigation to determine whether these needs could be communicated to distributors in a manner that would provide a more explicit and direct link between fulfilling these needs and potential economic benefit.

Cross-comparison between results from separate questionnaire parts is included to identify possible correlations between perceptions of individual product qualities and semantic evaluations from AttrakDiff questionnaire. This is done to explore whether the four groups (PQ, HQ-I, HQ-S, ATT) of AttrakDiff questionnaire evaluations have a link to separate product quality evaluations such as visual appearance, efficiency, ergonomics etc. For this purpose we construct a regression model where the dependent variable is one of the four AttrakDiff qualities and independent variables are presented in the form of weighted satisfaction values of product quality evaluations. Results from the regression model are presented in Table 2. Findings show that pragmatic quality (PQ) measure of AttrakDiff is positively related to satisfaction in “usability” and “understandability” of the product, although statistical significance of these effects is only at 0.05-level. The model also indicates that “visual appearance” has a strong impact on HQ-I, HQ-S and ATT scores of AttrakDiff (especially on HQ-S). This effect is significant at 0.001-level. In addition, overall ATT score was positively influenced by “ergonomics”. Despite encouraging initial results from the study questionnaire for intermediate parties, further research will be needed to establish more robust understanding and interpretation of preferences and experience based design approach perceptions of customers and distributors.
Discussion and Conclusion

B2B context introduces new challenges for experience-driven design, since designing solely for the end-user is not enough. Before we can start to improve employees’ satisfaction at the workplace by providing them experiential products to work with, we need to convince the intermediate parties, such as distributors and individuals doing the purchase decisions. The main goal of this paper was to point out the importance of including intermediate parties in UX based product development when dealing with B2B context. A simple model with simultaneous consideration of UX and CX targets is proposed as a way to derive experience based criteria for industrial products. Results from the questionnaire study indicate that intermediate parties in industrial product distribution chain are able to appreciate differences in hedonic qualities of different industrial products but these differences are largely dependent on visual appearance perceptions. Another finding shows that our sample of distributors

Table 2. Regression model results comparing semantic AttrakDiff evaluations
(1. Pragmatic quality (PQ): Describes usability of a product and how successful users are in completing their goals with the product, 2. Hedonic quality - identity (HQ-I): Indicates to what extent the product allows the user to identify with it, 3. Hedonic quality - stimulation (HQ-S): Describes how the product stimulates users and provides encouragement, novelty, interest and content, 4. Attractiveness (ATT): Describes a global value of the product based on the quality perception) of two pieces of warehouse equipment to evaluations of 14 separate product qualities of this equipment (Evaluation was based on 5-point satisfaction scale).

do not value potential benefits from most salient psychological needs (autonomy, relatedness and competence) in industrial product development but emphasize the importance of needs that are more directly linked to concrete product features (e.g. security and physical well-being). In addition to analyzing statistical data from the study, the aim was to capture general reception and feedback from the questionnaire format and its contents. The questionnaire was distributed and collected from 57 individuals belonging to equipment dealer party during two separate events in Spain and in Finland. Many respondents expressed surprise, because they never thought that industrial product qualities could be linked to psychological human needs or described as pleasant or attractive. Several individuals from the distributor group asked if they could have the same questionnaire for their internal use, which shows that we were able to raise their interest in experiential aspects of industrial products.

Library usability in higher education: how user experience can form library policy.

Alison Wiles¹, Stephen Roberts¹, José Abdelnour-Nocera¹.

¹ School of Computing & Technology, University of West London, St Mary’s Road, Ealing, London, W5 5RF, United Kingdom
{Alison.Wiles, Jose.Abdelnour-Nocera, Stephen.Roberts}1@uwl.ac.uk

Abstract. The university library is a large socio-technical system with a vital part to play in university life. It has been described as “the social and intellectual heart of campus”, with users now able to make use of both the digital and physical aspects of their library. Based on case studies in UK university libraries, this study aims to find out how and to what extent user experience forms part of university library policy, and how it can effectively be incorporated into it. Staff interviews and researcher-administered questionnaires with library users on campus will show the areas where usability issues occur and the gap between users’ experiences and expectations of using libraries. These together with analysis of library policies will aim to suggest the factors that a user experience policy should cover.

Keywords: University library, usability, user experience.

1 Introduction

University libraries will vary greatly in terms of design, layout, location and atmosphere meaning that the student experience will differ greatly from institution to institution. They are the places that students will go to not only to find and borrow materials, but are also places for studying, socialising and even for sleeping [1]. There are currently some 120 major universities in the UK [2], with approximately 1.8 million students enrolled as undergraduates in these institutions in 2010 [3]. There are also a further 275,000 postgraduates studying at UK universities [4], making a large and diverse user population for university libraries.

The phrase “the heart of a university” has been used to denote the high regard in which university libraries are held [5], and similarly they have been described as “the social and intellectual heart of campus” [6]. However more than 20 years ago, a study established that students had difficulties using their university library, with some experts believing they were “virtually unusable”[7]. Is this still the case in the early twenty-first century?

University libraries are moving rapidly towards a “self-service” culture. Whereas in the past university library staff would assist or actually carry out searches for books and literature, as well as helping with other library services, the onus is now on users to perform their own searches and find their own material using the interfaces, databases and search engines available over the world-wide web. Similarly, they are
expected to issue books using self-issue machines, and print their own articles. This has arguably simplified library use, while simultaneously bringing in a whole new set of problems.

Usability has been defined as “the appropriateness to a purpose of any particular artefact”[8]. It is a term widely used when referring to computer systems and their interfaces, but it can equally be applied to a non-computerised (or manual) system, or to an article such as a desk or building. Further to this, the International Standards Organization state that "Usability refers to the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use."[9]. The concept of usability can be applied to both the digital and physical spaces of a library, and it is vital that university library systems and interfaces, as well as the library buildings themselves are usable. Every university library will have the various systems and interfaces in place to support library activities with these systems potentially having thousands of users each with differing levels of computer experience, and also library experience. Similarly the physical library needs to be a usable space for both experienced and inexperienced users.

In common with other businesses and institutions, university libraries will have policies to cover areas such as circulation i.e. loan lengths and fines for exceeding these, collection development, user behaviour or conduct, and also computer use. There may also be policies which have the implicit aim of improving users’ experiences. Policies have been referred to as “...rules or guidelines that express the limits within which action should occur”[10]. Rather than stating what should or should not be done, policies establish parameters for the decision maker [11]. By having a user experience policy, libraries can make a pledge to their users to make their systems as usable as possible and to do this on an ongoing and regularly reviewed basis, so as to create the best user experience possible.

It has been argued that there will always be a gap in understanding between technology development and its use [12]. Petre et al’s [13] investigation into the total customer experience of e-commerce shoppers highlights this when it stresses the importance of thinking beyond just the web interfaces of a system to include other factors such as the delivery of the products or post-sales support. Customers have high expectations in these areas and if disappointed will not return to the website for further purchases, however usable it is. There is therefore potentially a gap between users’ expectations and those of the e-commerce operator.

In a study of the usability of London transport systems, Inglesant and Sasse[14] emphasise the need for system usability to be considered and made a priority at the policy design stage. This research centred on users’ lived experiences of using London transport systems such as the Oystercard and Congestion Charge scheme, with the researchers’ beliefs that each system is an ecology of interfaces and media types, not just websites. In information ecologies, the spotlight is placed not only on technology, but also on the human activities that are served by technology. They are systems of people, practices, values and technologies in a particular environment[15]. An example of an information ecology is a doctor’s surgery where doctors, nurses, receptionists and patients are the people involved, the practices are medical examinations and treatments, the values are to provide high-quality healthcare to improve health, and the technologies would include patients’ records systems or
accounting systems to track costs [12]. In the transport usability study, users of the transport systems were interviewed and asked to reflect on their experiences. Observation of users’ activities was also undertaken. This once again highlighted the gap between what users and policy makers expect from a system, with the researchers concluding that usability must be considered prior to the implementation of a system [14].

The following diagram shows that there are gaps between some of the expectations of library users compared with those of the policymakers.

![Figure 1. The gaps between user and policymaker library expectations.](image_url)

This builds on the concept of technological frames which identify the goals and problems that particular groups have with technology. Members of each of these two distinct groups, users and policymakers, will have similar yet not necessarily identical degrees of inclusion in the technological frame [16]. In a library environment users interact with both the library systems and the library building and have expectations in these areas, while similarly policymakers also have their own expectations. So for example users may expect to have a library system that is quick to use whereas policymakers hope it will fix the problems associated with the system it is replacing. Library users may want an environmentally-friendly building, but policymakers need to be aware of costs and may use cheaper materials.
2 Aim of the study

The theme of an ecology of interfaces applied to London transport systems can equally be applied to university library systems. Library systems can be complex especially to new students or those with less library experience, with some students even feeling high levels of anxiety when using the university library. They may also experience usability issues, and problems with the library environment, but may be unaware or unsure of how to report these or who to report them to. Similarly, library staff may simply be ignorant of the usability issues that students are facing on a daily basis, and also unaware of problems that exist within the library environment. There is a potential socio-technical gap between what librarians and technologists can offer and what is socially required by users [17]. Having a stated policy regarding usability and user experience can make this gap visible and is one way of moving towards a resolution of these issues.

Past research has looked at the library experience in terms of its environmental factors [1], and there have also been studies of the usability of the library's various systems such as the website utilising a number of research methods. For example Battleson et al [18] investigated the usability of a university library website by asking participants to carry out tasks and to “think aloud”, while Thompson [19] remotely observed users interacting with a library website. As previously discussed, researchers in systems in other areas such as transport have emphasised the need for a policy regarding usability and user experience[14]. Although it is not unusual for researchers to study the usability of library systems, past studies have tended to concentrate on one particular area such as the library website or catalogue. This study is taking a more holistic view and looking at usability in terms of overall user experience of the physical and digital libraries.

The hypothesis for this study is that a university library user experience policy will help to close the gap between user expectations and experiences. It is an exploratory multiple case study, and aims to find out whether and how user experience can form part of university library policy, and where it is absent how it can effectively be incorporated into policy. It also looks at the factors that the policy should cover by exploring the empirical foundations for such policies. This is investigated from the viewpoint of both the library users and the library stakeholders such as managers and other staff. The research questions that this study is attempting to answer are:

*How can user experience best be incorporated into university library policy?*

*What type of user experience factors should university library policy cover?*

3 Method

In order to answer these questions, this study requires data from both library stakeholders i.e. managers and staff, and also library users i.e. students, academic staff or others. Three university libraries were selected with each being treated as a case study. The cases are a range of UK university types with one being a post-1992
(or new) institution, which is a university that was formerly a college of higher education or a polytechnic, but acquired university status as the result of a 1992 act of Parliament. The second case study is a longer established university which is also a member of the 1994 group of research universities, a collection of 13 internationally renowned, research-intensive universities with the aim of promoting excellence in research and teaching [20]. The third is a specialist institution focused on postgraduate study and research. Having these three types should add more range, depth and interest than if similar types were investigated.

Library users at each of the cases were surveyed to reveal their opinions on the library’s usability and their own experience of using it. This was done via a questionnaire administered personally by the researcher by stopping and asking students on campus. This is because questionnaires can have a low response rate unless carried out in this way [21], and also because university students are often asked to complete either paper-based or web-based questionnaires, and as a result some universities are actively trying to limit the number of them being carried out. Participants were selected in the library, and although this resulted in a convenience sample, it has been noted that convenience samples are very common especially in social research [22].

The questionnaire firstly asks for background information about the student, for example age, area of study and gender. There are then questions about library use in order to decide whether the participant is a regular or infrequent, experienced or inexperienced library user. The next part of the questionnaire is adapted from Koohang and Ondracek’s [23] research into users’ views of digital libraries. The questionnaire designers state that it is “...a highly valid and reliable instrument”. There is a series of Likert scale questions assessing the user’s current views on library usability based on 12 properties, followed by more Likert scale questions evaluating the user’s perceptions of the importance of each of the 12 properties. This means that it is then possible to calculate the gap between the user’s experiences of the usability of the library and their expectations of its usability. The participant is asked to think about the library building and its systems as a single entity when answering the questions. The 12 usability properties include factors such simplicity – whether the library is simple and straightforward to use, user control – whether the user feels in control of his or her actions in the library and knows what to do, and navigability – whether the user can find his or her way around the library and its systems. The other nine factors are:

- Comfort – whether the user feels at ease using the library
- User-friendliness – whether the user believes the library is user-friendly
- Adequacy – does the user feel the information accessed in the library meets their needs?
- Consistency – are the words, terms and actions used in the library consistent?
- Access time – can the user find what they need in a reasonable time?
- Readability – is the information accessed readable and uncluttered?
- Recognition – whether the user recognises the features and functions of the library
• Visual presentation – is there signage and text to grab the user’s attention?
• Relevancy – is the information accessed in the library relevant to the user’s requirements?

Finally the participant is asked for any user experience or usability issues that they have encountered. Forty questionnaire responses have been collected at each university. Data collected was analysed statistically using the software, Statistical Package for the Social Sciences (SPSS).

Key members of staff were interviewed at each library in order to gain information about user experience policy. Usability issues are also covered in these interviews, with staff asked to discuss any known problems that occur in library and with its systems. The questions were open-ended in nature so that interviewees can be asked about facts and their opinions [24]. Three interviews are to be carried out at each library, ideally with a manager, a frontline member of staff, and an information technology or systems staff member. The interviews were recorded, transcribed and then analysed via a qualitative content analysis approach which involves searching out the underlying themes in the materials being analysed [22].

Analysis of any policy documents is also to take place at each library to ascertain what has been written regarding policy in relation to usability and user experience. Additionally a survey of all UK university libraries will be carried out to find out what policies are in place across the sector. This will be done by looking at each library’s website.

As a part of each case study, empirical data is required to “set the scene” at each library. The researcher observed the day-to-day working of each library to help gather background information and to form specific interview questions for staff.

4 Findings and anticipated results

Currently data has been collected at the three cases. A total of 120 questionnaires have been carried out, 40 at each of the three cases. Library A is the new university, Library B is the postgraduate specialist institution, and Library C is the member of the 1994 research group of universities. Staff interviews have been carried out at Library B, and the survey of policy documents is underway.

4.1 The libraries

Library buildings remain central to library services [5], and the allocation of space and facilities therein has impacts on how the university library is used. Students now expect different zones for individual silent study or group work. They also expect personal computers (PCs), printers and even café facilities.

Library A is housed in a building attached to other parts of the university. It has four floors, with the ground floor containing a careers advice centre for students, along with a series of library self-issue machines. The first floor is set aside for silent study and also has a number of PCs for student use as well as shelves of books. The library
helpdesk is on the second floor along with the bulk of the PCs and printers available in the building. Staff offices are also based here. The rest of the space is given over to books. The third and fourth floors also contain bookshelves PCs and study areas, but the fourth has provision for group work with some seminar rooms as well as large round tables with screens around to help keep noise to reasonable levels.

Library B was built in the early 1990s, is a stand-alone building on campus, and has three storeys. The ground floor has a number of seminar rooms and an area containing food and drink vending machines with a large table. The first and second floors are similar in layout, and both have individual workspaces with PCs, seminar rooms, and bookshelves. Staff are based mainly on the first floor, with helpdesks and self-issue machines here too. Quiet study areas are on the second floor.

Library C is situated centrally on the university campus and has recently had a large extension added to increase the number of study spaces, PCs and group study rooms available to students. The library is now a mixture of the “old”, more traditional library space, and the “new” state-of-the-art space. There are five floors in the building with silent study and group work areas. Level one is where the main entrance, self-issue machines and staff offices are located, and there is also an area containing food and drink vending machines along with seating and tables. Books and PCs are distributed across the five levels, with the third floor having a more relaxed work area containing sofas and armchairs.

### 4.2 The questionnaire participants

Questionnaire participants fall into three separate age groups with 50% aged 18 to 24 years, 37% in the 25 to 34 years age group, and 13% aged 35 years or older. Sixty per cent of participants were male and 40% were female. The vast majority of participants (84%) described themselves as frequent library building users, with only 6% saying that they hardly use the library building, while 55% were frequent users of the library website.

Fifty-nine per cent of participants were postgraduates, with 31% being undergraduates. The other 10% of the sample was made up of research students, staff and alumni. The vast majority of participants, 94%, were full-time students, and the most popular study subject areas were Engineering (24%), Business (18%), and Natural Sciences (12%).

### 4.3 Questionnaire results

The three main uses of the library buildings are:

- Borrowing and returning books
- Individual study with library materials
- Accessing computers

While the three main uses of the library website are:
Searching the catalogue for books and materials
Searching the library databases and e-journals
Browsing electronic books (e-books)

Looking at results in terms of user expectations of library usability, the three areas where users have the highest expectations are:

- Relevancy
- Adequacy
- Simplicity

This means that participants expect the information in their library to be relevant to their needs as well as adequate for their needs. They also expect the library and its associated systems to be simple to use.

Lesser expectations are in the following 3 areas:

- Recognition
- Consistency
- Visual presentation

Meaning that participants are less concerned that they are able to recognise the features and functions of the library, or that the words, terms and actions used in the library are consistent. They are also less concerned that there is signage and text to grab their attention.

These results show that participants are concerned about the information they access and how they access it, and less concerned about the appearance and functionality of the library and its systems. And looking at the three cases separately, the lists of user expectations are very similar suggesting that students have the same issues and concerns regardless of where or what they are studying.

The data can also be analysed by looking at the gaps between user expectations and experience of using their library. Again the results are similar for the three universities with the smallest gaps tending to be as follows:

- Comfort
- Control
- User-friendliness

So participants’ expectations and experience are closely matched in terms of feeling at ease using the library, feeling in control of what they are doing, and feeling that the library is user-friendly.
The largest gaps between expectations and experience tend to occur in these three areas:

- Access time
- Adequacy
- Relevancy

It has already been established that participants have high expectations as far as adequacy of information and relevancy of information. However, these results show that their high expectations in these two areas are not being met by their actual experience thus showing where improvements are likely to be required. The largest gap concerns access time. It would seem that it takes participants much longer than they would like to find the information they need, and again this is an area where improvements are needed.

4.3 Staff views

Interviews with staff at library B have shown that usability testing is carried out whenever possible at the library, but that this is often done in an informal way, for example by asking students to look at a new interface or system and then asking for feedback. Sometimes students volunteer information when a change is made, by telling staff their opinions, and a library Facebook page encourages feedback.

Generally staff believe that a stated policy on user experience is beneficial, and that formal usability testing via methods such as focus groups is valuable. But they also point out that while it is possible to feedback issues to a software supplier, the interface of a library software package will not usually be changed to meet the concerns of one library alone.

Library staff help and advise students with computerised systems such as the library catalogue, and also the manual systems for example the shelving classification system. They note that the library can become busy and at times there is a lack of workspace for students.

5 Discussion

Data collection in this study is still ongoing, and as yet it is not possible to fully answer the research questions or to make conclusions.

It has been seen that library users at the three cases value the adequacy and relevancy of the information available in the library, and are less concerned about the appearance and functionality of it. Further analysis of the questionnaire data by age, gender, area of study etc will add further insights, and interviews with staff will no doubt show similarities and contrasts with the students’ opinions. Opinions of library usability are lived experiences in that the students or other users have used the library to try to achieve a particular goal. This goal could be as simple as finding a book on a particular topic, or as complex as writing a literature review for a Masters dissertation,
but it goes beyond their experience of using a computer to include other technological and human factors along with their own experience, capabilities and values [14].

If the university library is viewed as an information ecology, it has students, academic staff, librarians and other support staff as the people involved. Its practices are the provision of information in various formats both physical and digital, while its values are to provide this information in such a way that it is easy to access, readable, relevant and adequate.

Figure 2. Creating a library user experience policy.

This study aims to shows that the creation of a library user experience policy begins with the identification of the socio-technical gap between experiences and expectations. This is when library usability opinions from staff, students and other library users are gathered, and analysed in conjunction with the existing library policies, and the existing functionality of the library building and systems. The policy needs to be a commitment to library users to continuously strive to improve the library systems and interfaces, and in order to meet users’ needs its impact must be assessed on an ongoing basis.

Adjusting the design target of life-cycle aware HCI in knowledge work settings

Heljä Franssila, Jussi Okkonen

University of Tampere, School of Information Sciences
Kanslerinrinne 1, FIN 33014 University of Tampere, FINLAND
{helja.franssila, jussi.okkonen}@uta.fi

Abstract. The goal of this work-in-progress paper is to consider the utility of current theoretical and methodological HCI and work analysis approaches in understanding and supporting knowledge workers in their coping with contemporary computing ecosystems at work, and pinpoint the limitations of the design target formulation in current HCI approaches. The new approach discussed is to focus the design efforts, instead of technical artifacts, into the observation, understanding and development of computing practices. Alternative, emerging conceptualizations and methodological options to study and advice the development of everyday computing practices in knowledge work is proposed.

Keywords: knowledge work, computing practices, design, use life-cycle

1 Introduction

When considering both popular and scholarly discussion related to the most prominent determinants of work wellbeing and performance of contemporary knowledge workers, certain themes recur with accelerating frequency. Information overload, interruptions, multitasking, always-on availability and the growth of the computing ecosystem versatility are characteristics of everyday work potentially challenging the knowledge worker’s sense of control in their work. All of the above mentioned challenging phenomena are more or less related to interaction between the human and the computing environment. Computing environment stretch the operational limits of human attention, concentration, memory and self-control, be it subjectively experienced or objectively measured.

The goal of this conceptual work-in-progress paper is to consider the utility of current theoretical and methodological HCI and work analysis approaches in understanding and supporting knowledge workers in their coping with contemporary computing ecosystems at work. Special focus is to observe how the everyday computing practices of the knowledge workers is addressed in the HCI and work analysis literature. We examine how the target of design is conceptualized in HCI and in certain approaches of work analysis, and how the positioning of design target may limit the expected results of work practice design and development efforts. After that we pro-

© Springer-Verlag Berlin Heidelberg 2011
pose an extension of the design target of HCI that we find relevant when analyzing and developing computing practices in knowledge work. To ground the feasibility of the proposed approach we discuss rather new data collection methods which serve the goals of the extended target of design in HCI. We also acknowledge certain concepts from contemporary HCI and work analysis as applicable in the newly framed HCI in work settings. The discussion is motivated by our recently started research project called “Construction of evaluation and development approach for information ergonomics in knowledge work”, which is funded by Finnish Work Environment Fund.

2 Computing work practices in HCI and work analysis

The goal of HCI has been at least traditionally to understand, design, evaluate and implement interactive computing systems for human use. In work settings one of the more detailed goals has been enabling more productive work practices and processes [1]. HCI in work settings seeks to make work (and life) involving computing fit better with plethora of human characteristics. The time-scale of design and research approaches in HCI have lately been extended to cover also stages after the technical implementation and adoption of technologies. These stages are conceptualized as appropriation, configuring and design-in-use (see e.g. [2-4]).

The design goal of HCI - more successful interaction and use - however seems to be focused or framed in a certain way both in HCI research and practice. When considering design and development efforts, it seems that while the methods of practical HCI design aim to target interaction, most of the efforts of the design materialize as modified designs of the technical applications and devices - the computer side of the HCI concept dyad. Users and their activities, emotions and even biofeedback are shadowed, recorded, analyzed and modeled, but the implications and conclusions derived and the practical design recommendations and requirements given typically address only the computer or application side, not the human user side. This tendency can be observed for example in the literature reporting the application of participatory design in real world development projects. It is practically impossible to find a reported participatory design project related to the application of information technology, where the development effort would not have been motivated by an organizational, predetermined need to plan, develop, purchase or modify the information technological solution per se. Projects having as a core design goal to enhance and develop the utilization of existing technologies practically does not exist. Even the research interest to study the realization, details and lifecycle of IT use after system deployments in organizational contexts is very scarce (the rare exceptions are [5],[6],[7],[8],[9]).

There’s also strong tendency to try to model how the users will use the technical artifact in the future, and to equip the artefact with technical affordances that potentially could fulfill emerging user needs and preferences (e.g. infrastructuring proposed by [10]). When considering the quality of long-term HCI from the human side, this is somewhat desperate approach: majority of the development efforts stop when the application is released and not fundamentally changed any more (customization and tailoring functionalities are considered as features of mature application). The com-
puter side of the relation is left practically untouched after the release of the application. After this, there’s only the human side of the relation, which can be influenced.

One potential reason for the practical non-existence of approaches which seek to develop the user behavior in longer term and the human side of the HCI dyad is that underlying nearly all examinations of human-computer interaction pitfalls is the unexpressed assumption, that if the interaction fails, the weak or even evil party in the interaction process is the computer, not the user or his/her activities. Characteristics of the computing solution do not fit e.g. the work practices of individuals and groups. It is the technical solution, which needs to be fixed and which requires changes, not the human or the human computing practice. The evolving human computing practice is something that is often left to develop on its own. Often even unrealistic “abilities” are expected from the technical applications, like alertness to user’s errors and capabilities to steer and advice user while he or she is computing whatever goals or tasks at hand.

Another characteristic of the conventional HCI is that it might be interested in studying interaction between human and computer in rich, “wild” computing ecologies, but typically design implications and recommendations derived from observations concern only a limited facet of the computing ecosystem the user operates, namely certain service, application or feature. The chains of real world computing activities, where the computing ecosystem is in versatile ways utilized by the user, are not considered as a development target per se. However, we believe that the human user can and will do a lot to influence the quality of HCI phenomenon after the deployment, during the life-cycle of interaction with the computing ecosystem, even though no iterations or considerable changes to the technical computing ecosystem (software and hardware) are deployed anymore.

3 Unknown practice of knowledge work

Contemporary knowledge work and knowledge workers are very often characterized as creative, boundary less and free. Knowledge work and workers are often pictured as contrary to the factory workers whose manual work is highly structured, repetitive, without freedom to choose the best method, place and time for the work execution. Knowledge work and especially their concrete macro and micro working and computing methods and practices are most often left untouched and unexplored – both in practice and in research. Working methods, habits and practices of knowledge workers seem to be a great black box in the research literature. Thomas Davenport [11-12] is one of the rare scholars who have questioned this immunity of the knowledge work and knowledge workers’ working methods and practices for research scrutiny.

It seems that continued, post-deployment IT use and its development per se in work contexts is not a prime interest of any HCI approach. The studies of appropriation, configuring and design-in-use address the rather long post-deployment period of use life-cycle, but the main interest is to understand and advice the design of deployed technologies or technical means to enable their technical adaptation. The detailed paths of computing activities of a user across different applications and the develop-
ment potential during the life-cycle of everyday computing practices are considered rarely. We propose, that understanding computing micro-practices in detail is central when considering the work efficiency and control experiences of end-users, and when trying uncover the phenomena like the experience of information overload and interruption. HCI and work analysis seems to resist or at least hesitate to formulate human computing practices as a goal of design per se.

4 Promising conceptual and methodological approaches for more life-cycle aware HCI

When considering the understanding and the systematic development of computing practices at work, the turn to the practice and the turn to the wild [13] in HCI provide promising conceptual tools. Detailed ethnographic descriptions of work practices may serve appropriate grounding for unfolding of actual computing conventions and methods knowledge workers apply. In the studies conducted in the tradition of workplace studies [14] and distributed cognition [15] have provided vivid accounts how users and communities in workplace enact to total work environment and its computational and representational resources. In the practice tradition there is emerging quest for not only analysis but also for systematic development and reforming of social practices when applying technology into work [16]. The cognitive work analysis is explicitly concerned about how HCI can enable designing for worker adaptation [17].

A sample of analytical concepts can also prove powerful when descriptions of work to enable systematic development of computing practices in work are pursued. The application of the concept of computing habit in IS research has devoted more attention to the human side of HCI dyad, even though so far the approaches have mainly been explorative and descriptive, not design or development oriented [18]. Computing habits are controversial when considering efficiency of human-computer interaction. Habits make any activity effortless and fluent, but at the same time they are very sticky and conservative, hindering possibilities to learn new, enhanced methods and practices [19].

Profiling basic, industry-independent knowledge work processes and knowledge work types has been provided scantily, but the account of Davenport makes an exception [11]. Davenport tries to formulate a set of basic working modes of knowledge workers, and presents a typology of knowledge workers. In addition, when trying to find a unit of work to serve as analytical basic element for characterizing knowledge work practice in meaningful granular level, the concept of ensemble is proposed. Ensembles are units of work which are concrete enough to be distinguished from thick account of work, and conceptually they lay between the unit of action and the unit of activity [20].

Promising conceptual tools for development oriented analysis of knowledge work, knowledge work practices and computing practices in work can be found from rather unexpected direction. In the context of lean management philosophy and development practice, treatment of information as a resource of work process and practices has emerged. Powerful categorization of different kinds of wastes in lean management
approach is applied to the analysis of work practices which involve manipulation of information [21]. Even the long abandoned tradition of taylorism and especially its most well-known development method, time-and-motion studies, could be successfully adapted to the study of work processes and practices which comprise of information flow manipulation. The profound developmental goal of time-motion studies was and is even nowadays to equip workers with better and more convenient working methods.

The application of above mentioned, not very conventional analysis frameworks of work and computing practice are becoming feasible because of the emergence of new empirical methods of tracking the details of everyday computing practices in work. Portable lifelogging devices (e.g. Vicon Revue) and associated analysis software, tracking software for capturing, logging and analyzing moment-to-moment screen activities, and portable, mini-sized video cameras leaving both hands of the user free provide powerful but unobtrusive means to study naturally occurring micro-practices of computing in work. They provide rich and objective measure about what happens in the concrete level of computing operations. This data, when applied as the source material for the analysis of actual computing methods can open up totally unrecognized possibilities to recognize the details of computing habits and micro-practices, and to understand the determinants of efficacy of human-computer interaction in the service of knowledge work.

5 Conclusions

In this conceptual work-in-progress paper we have discussed kind of black spot of HCI and work analysis, namely the inability to systematically address the development on everyday computing practices of knowledge workers. When considering the life-cycle of use of any technology, the post-deployment period is the longest phase of the life-cycle of use. During the long post-deployment period, the everyday computing habits and practices evolve, and often very rapidly freeze – regardless of the affordances designed into the technical artefact potentially enabling a more sophisticated and efficient use. We have observed that development of computing practices and habits of individual users and user communities in work organizations are not central design targets of current HCI or work analysis efforts. This is an unfortunate limitation, considering the critical role the actual nature of use plays in the shaping of the overall impacts of computing for the qualities of work processes and experiences of the knowledge workers [22]. Therefore, we propose that a central new design effort focus of HCI and work analysis should be the understanding and development of everyday computing practices of knowledge workers in their “as-is” computing environments. In addition, we proposed emerging and promising conceptual and methodological approaches to address the shortage.

Abstract. Mobile probing is a method, which has been developed for learning about digital work situations, as an approach to discover new grounds. The method can be used when there is a need to know more about users and their work with certain tasks, but where users at the same time are distributed (in time and space). Mobile probing was inspired by the cultural probe method, and was influenced by qualitative interview and inquiry approaches. The method has been used in two subsequent projects, involving school children (young adults at 15-17 years old) and employees (adults) in a consultancy company. Findings point to mobile probing being a flexible method for uncovering the unknowns, as a way of getting rich data to the analysis and design phases. On the other hand it is difficult to engage users to give in depth explanations, which seem easier in synchronous dialogs (whether online or face2face). The development of the method, its application to the two projects, and the challenges and potentials which were found are discussed in this paper.

Keywords: Human Work Interaction Design, Cultural & mobile probes, online empirical data gathering methods, ICT, designs for learning

1 Introduction - Research Area and Focus

It is difficult for a designer or researcher to ask questions pertaining to user’s work process, task or similar, if the existence of this process or task is not known to the designer/researcher. Similar, for a user, it is difficult to recall aspects, no matter how relevant they may be to convey, if these are not touched upon in the dialog.

One of the authors had through previous experience from practice (research-based design and research-based consultancy) found herself in this paradox of trying to get to the “heart of things”. It seems that applying traditional qualitative methodologies to a digital and online setting does often not bring about much information besides what is being asked about. Moving to more ethnographic approaches as observations and task analysis can be difficult to do online, and requires a lot of hours for both collecting and analyzing data. With methods as online interviews and focus groups, it has been difficult to bring forward the so called non-knowledge. This does not mean that the knowledge is tacit to the users; but simply that when the questions are not asked; the issues are just not touched upon in the digital / online interviews, focus groups or a “describe your workflow” situation.
The cultural probes method is a more explorative approach, which on previous occasions has provided valuable information, in particular when combined with other inquiry- and interview-based methods in traditional face-to-face situations [12]. Consequently, it became relevant to look for a way to transfer these experiences to digital and mobile methods.

Based on the before mentioned difficulties with getting to non-knowledge, the first research question was to see if mobile probes can provide an adequate way forward. Secondly, to investigate, which adaptations of the method were useful when gathering qualitative empirical data from end-users, to be applied to the design process.

Two projects have been involved in this research so far. In 2010 the method was used in a project on mobile learning, where school children from the same school in 8th grade participated (young adults at 15-17 years old). Here, the objective was to gain knowledge from users, in order to inform the design process of a mobile application to be used in the educational system. The other and most recent use of the method was in 2011, where the participants were employees from a major Danish consultancy company. This project had a dual objective: One perspective was to learn about the employees’ standpoint (feelings about) and use of the existing knowledge sharing platform, in relation to the concept of knowledge sharing (what was understood by this term), and their knowledge sharing strategies in practice. The project also wanted to discover and map possibilities for mobile support of the practiced concept of knowledge sharing in the company.

A common focus area, on the practical level of these two involved projects, has been the need to acquire knowledge directly from the end-users; on their work tasks and processes related to knowledge sharing in general and on their use of digital media, more specifically mobile phones / smart phones.

The tasks under investigation were also carried out in a very mobile or flexible environment. For example the employees in the consultancy case, worked from different locations, and only sometimes at the office. Similar for the young adults, who were in and out of school, at home, with friends and so forth. Both projects wanted information about a specific group of people (contextual information) and their current use of their smart phones in general and in relation to how future use-situations could be. In the situation of the consultancy the employees were even situated in different countries, making the need for a digital empirical gathering tool, even more eminent.

Research findings point to that applying mobile probes in an almost qualitative interview fashion, utilising the users own mobile equipment can be a very rewarding for the projects in term of uncovering non-knowledge. However, in some situations the mobile probes are seen as intrusive to daily practice (understood as too time consuming for user to deal with).

In the following, a brief presentation of the concept of non-knowledge and a discussion of its implications for this paper is given. Afterwards, a presentation and discussion is given of the literature and history on cultural probes as it relates to the development of this mobile probing method. Then the first research design considera-
tions are outlined in the first use of the method. Afterwards the second project and its methodological use are presented, followed by a general discussion on findings related to the mobile probing method.

2 Non-knowledge

Non-knowledge is the knowledge that depends on context, social relations and artifacts in order to become codified.

An integral aspect of the mobile probe method is its ability to help gather otherwise hard to handle knowledge. This paper does however not offer space nor is it the place for a long discussion on the differences between tacit and explicit knowledge, on codified and uncodified knowledge and on focal and subsidiarily knowing, to put it in Michael Polanyis terms, and the often used quote that “There are things that we know but cannot tell.” [16] We would however, like to establish this frame, that the knowledge form, which is addressed here, is often both contextually, socially and technologically tied, which means it can be very hard, even impossible, for a participant to describe; as work processes and tasks of everyday life is tied to complex network of actions and interactions, thus it can be difficult to realize the causalities; which relations makes which difference.

If space permitted, it would make sense to here also discuss and refer to Ed Hutchins distributed cognition [17], as well as the larger body of knowledge sharing literature, for example Nonaka and Hirotake [18], as the concept of non-knowledge as it is used in this paper is closely related to the codifiability of interpersonal knowledge.

For the work presented in this paper, the postulate is that a part of the code is kept outside the person “holding” the studied knowledge. This means that this “outside”, whether artifact or human, needs to be documented or brought into play, if a larger piece of the sum-knowledge (which is not an a priori definite sum) is to be shared or understood in design and design-research. This makes it necessary to identify relational ties between the studied knowledge and the context and artifact that it is interwoven with. Without gathering this data, the state of the knowledge is in danger of getting perceived as everything is tacit knowledge, which cannot be made explicit, while in fact some is pre-codified and can be “talked about”, when connected to the “outside” documented nodes.

With a somewhat different objective, though not far from, Lotte Darsø in one of her earlier papers with the title: Is there a formula for innovation? Defines and describes non-knowledge as part of her model for innovation. “Non-knowledge deals with that which we know, we do not know; that which we do not know, we do not know; and finally that which we did not have a clue about, that one could know. The problem with non-knowledge is, that is it an uncertain and fear-provoking area to be in, and this leads to, that most people prefer to withdraw to safer grounds.. [and she continues, when referring to how we can work with non-knowledge] .... This is pri-

1 Research on the first project, with a focus on the domain findings: designing for mobile learning, is published in [11].
marily done by asking questions – and keeps asking questions.” [19, p.6]. (The term non-knowledge as used by Darsø has been developed in collaboration with her then ph.d. advisor Henrik Herlau).

An integral aspect of this view, is that the design-researcher, who is in both an analytical and design activity of getting to know the users, context and technologies, and who is mindful to documentation in-situ; also need to think about: what has not yet been written, talked about, taking pictures off, which relations did I not see, what can surprise me; and what can I learn now, that I could not predict before?

3 Methodological Considerations

The Cultural Probes method was originally introduced to HCI by Gaver, Dunne and Pacenti. The method was developed using probes such as maps, postcards and other materials that were designed to provoke inspirational responses from elderly people in diverse communities [4]. The method provided empirical user generated data, whose content could not be predicted and which held valuable information about emotions, reasons as well as visual representations. This data collecting process preceded the design phase and contributed to the qualitative knowledge-base about users. [4,5].

The typical cultural probing process has used a large degree of openness and anonymity. For example the postcard could contain a statement or question, as open as “what is a living room to you”, and some would return with a description of their own living room, others with a dream scenario, some focus on the layout, others on what on activities etc. etc. As the post card would be pre-stamped or handed in to a box, the anonymity would be well preserved.

In the presented projects in this paper, there was a need know something about a known and pre-defined user group, within a relatively well defined area, on the other hand the cultural probes perspective of openness was also desired. Interviews and focus groups would be feasible ways, but could not stand alone. A number of methods inspired from ethnography are often too expensive or otherwise resource consuming to implement in large scale for many smaller research projects or development projects with research involvement.

This primarily concerns two aspects: time used to plan, conduct and analyse the data gathering, and time usage required from the participants. The latter was especially of concern in the consultancy case and would be in many similar situations. A hybrid probing method was thus selected based on both appropriateness, but also scaled to the project size.

Others have used hybrid probing methods, as using them in a game-environment, which in the cases listed significantly increased the number of responses [13], and the cultural probes have also moved to digital probing materials and in recent years in particular to focus on mobile probes using mobile phones [1]. Iversen & Nielsen applied mobile phones, as they needed to utilise a media which was suitable for children [7]. In a Finnish study by Hulkko et al, the aim was to make the probe more accessible in all contexts. Their research was rooted in a customer survey perspective, investigating the buying habits and decisions people make when buying clothes (thoughts
and visual impressions). Consequently, they too digitized the cultural probes concept, handing out mobiles with attached cameras, with the intention of getting empirical data gathered in-situ [6]. The review of mobile probes studies also indicates that the method is predominantly used in the consultancy domain as opposed to the research domain where it can be focused more on input to practice. For example, one company developed a mobile based 'probe pack'. A tool for collecting data, with the purpose of reducing development and execution time associated with the use of probes [10].

There are two arguments for using digital probe forms: it provides means for getting access to situated information, and users today recognize and are motivated by mobile phones in the same way as disposable cameras and post cards was [7].

The digital based probes are sometimes linked to Experience Sampling, used in a form of non-present observation of the everyday life of respondents. Experience sampling was originally described as: “to identify and analyze how patterns in people’s subjective experience relate to the wider conditions of their lives. The purpose of using this method is to be as “objective” about subjective phenomena as possible without compromising the essential personal meaning of experience” [14]. It should however be noted, that technology focused data gathering, using handed-out technology will not provide a valid technology usage picture. Instead it will most likely give insight into the adaptation and acquisition of new technology. While the Experience sampling method seeks to minimize this by prompting for in-situ, descriptive data Mobile Probes uses a semi structured approach, combined with non-intrusive technology. One of the guiding questions for using the method in the mentioned studies could therefore be phrased as; if mobile phones are handed out as part of the empirical data gathering process, and the data gathering process is about mobile phones: how natural would their use be to their everyday lives?

In the above studies the participants were given new tools (hard-/software), which they had to learn to use, before being able to respond on the probe tasks. If such a strategy is applied, it may seem extensive and intrusive to the participants, because learning a new media and being able to use it actively, is a process that takes time and energy. Even if the learning curve over time becomes shorter for some user groups (that is the time needed for acquiring the ability to use a new smart phone, may be relatively small for some user groups) it is not part of a natural work situation to carry several phones; to work on one phone while carrying out the usual digital tasks and then shift to a new phone to send data to the research project.

In the projects, the mobile phone was not only acting as an agent for acquiring empirical data (as the situation in hitherto mobile probe settings as seen above) but was also the technological medium for which data should say something about (mobile learning and knowledge sharing / management). Consequently, not only the content of the data but also the ways in which data was delivered and handled, provided a valuable dimension for investigating mobile use. It would not make sense to give the participants a new phone, with different operating systems and apps than they usually use, as it would say less about their everyday informal strategies.

Probes have often been applied by probing people randomly, with pre-designed probes and answer-channel (text, picture etc) or by allowing participants to choose time and answer-channel [4,5,6]. There are no immediate follow up on the returning
data from the participants’ [1]. Boehner et al. argue for probes that work as an open conversation with the participants. A conversation, where the researchers’ contribution is a response to what was expressed in the answers coming in from the participants’, instead of making representations that delimit the design space [1]. As a result, a more dialog oriented approach, seem appropriate [2].

In a semi-structured interview, the interview guide is pre-formulated [8]. The guide sets the scene, but enables the interviewer to come with follow-up questions, to guide the participants in new directions or to even omit subjects from the pre-formulated guide if this is relevant in the context as the interview takes place.

An important aspect of the cultural probes method is that it does not aim at generating data, which should go through a traditional qualitative analysis; rather the objective is to make the researcher sensitive towards the emotions, experiences and causalities of the participating group [4]. The initial focus of the probes has thus never been on the development of products, but on new understandings of users and their use of technology [5]. However, in the research and development projects outlined in this paper, the objective has been to understand users’ application and utilization of existing technology in order to make future design decisions or strategies of design. This may influence the original method in terms of how the received data from becomes sorted and analysed. In “Moving from cultural probes to agent-oriented requirements engineering “Anne Boettcher discuss data collection in social environments via cultural probes and uses socially oriented requirements analysis for informed technology production [15]. However, mobile probing in these settings does not take place in a vacuum, but in projects were a number of other design activities take place. The intention would not be to let the responses to the probes be subjected to a direct translation into a design, or to see them as “correct answers to a problem”. The idea is rather to support the codification and understanding of all data from all methods; to rest on a better foundation of users, their opinions and emotions, and their everyday practice.

In summary and for the outlined contexts, the combination of methods could make it possible to expand on the dialogical aspect, as the mobile phone enables a more flexible probing process than pre-printed post cards and similar material, using generic programs familiar to the participants (as sms, mms, mail etc.). Also, where interviews and surveys have a more retrospective character and ethnographic or anthropological research often requires a “researcher to go native”; in this kind of mobile probing the researcher could ask to the “here and now” of a situation and alongside the actual answers, receive valuable metadata pertaining to contextual technology usage. The probes are part of a larger set of methods applied in pre-phases and data from the probes are analysed and joined with data from the other methods.

4 First Use – Mobile Learning in Schools

Through ministerial funds a project partnership was formed between a broadcasting corporation and two private companies with the objective to develop a learning application for Smartphones. The vision was to combine digital information from archives with current information, and thereby support learning in multiple disciplines (as
relating historical and current news shown on the phone as the user moves in the city spaces). One of the authors of this paper was invited as a research-based consultant within IT didactical design and two other authors participated as research assistants, where they applied the data in their master studies. IT didactical design refers to the theories, models and practices of teaching and learning supported by IT, focusing on the process perspectives in educational design, as activities relating to both (re-)designing, planning, running, adapting and evaluating learning processes and spaces for learning.

The pre-phase began in the spring of 2010. However though the researchers finalised the pre-phase, the partnership between the companies dissolved and the project itself was never finalised. Nevertheless, the process and findings were methodological relevant.

The project’s primary audience was students at 15-17y. According to the project description: in 2009 more than 98% of these Danish students were using mobile phones, one third send photos, videos or similar and roughly one in five surf the web using their mobile phones. However, in 2010 very little was known about the informal strategies, the cognitive and subjective processes, as well as the reasons and motivations for mobile applications use. A small investigation based on the Cultural and Mobile Probe method was seen as an adequate way forward at the same time as workshops and low-fi prototypes were designed and evaluated. The research design was build on the assumption that the probe data would spread light on what are the positive and negative user experience elements, and how these components influence the students’ choice and learning strategies.

Access to the potential participants, was gained through the headmaster in order to get permission to contact them during school hours. All students in the age group were presented to the project and encouraged to contact the researcher if they wished to participate. The final participants were chosen from those who replied, based on criteria’s related to their access to the technology, and their experience with Smartphones. Subsequently four students from the same high school were chosen, adopting a homogenous and typical sampling based strategy [2].

The probing took place over a period of seven days in which the participants received text messages with various questions about their use of Smartphones, and received tasks they should address utilising various media and generic Smartphone functions. The participants received three text messages each day. The first question was typically sent in the morning, the second at noon, and the third around 6 o’clock in the evening. The first two questions were almost always the same for all participants, whereas the third was often used as a follow-up question to their previous responses, making it individual. Three questions per day enabled some of the positive aspects of semi-structured interviews, where you can make inquiries in to the essence of opinions [8].

During the seven days, 81 tasks were sent and 74 answers were received. The answers were primarily text messages, but also many pictures / screen shots. (table 1 and figure 1).
From an analytical perspective, the Mobile probe method objective was not to reach a single unambiguous answer or solution, but rather the responses should let the researcher become inspired by the participants [1]. With the aim to support the project’s rigidity in the analysis phase, while keeping a user-centric focus, user experience goals and cognitive process variables were applied to the analysis. The cognitive processes were identified as: attention, perception & recognition, memory, learning and problem-solving, planning etc. The user experience goals were identified, as: satisfying, enjoyable, provocative, boring, etc. (All derived from [9]).

The multi-modal nature of the responses presented a number of challenges during both the collection and analysis process. The primary challenge was to organise the data in a way that would give it a uniform structure and expression, in order to compare answers and reveal trends and relations. Data also had to be recorded and stored during the collection process, in a way that supported the interview-based probes approach. Consequently, the project identified "probe managers", sending tasks to the participants and communicating with them when necessary. To facilitate this, an online data collection site was used, where answers and thoughts on the ongoing process was shared. This site allowed simultaneous work on the data.

For example a simple text-based table was used to store and organise both the predefined guide and questions, as well as the participants’ answers; Day 1, Question A, participant 1, 2, 3, 4 - Question B, participant 1, 2, 3, 4, etc. Organising data this way enabled an ongoing preliminary exploratory analysis during the collection phase [2].

This overview helped qualify the follow-up questions, and showed if it was necessary to deviate from the original questions. After the probing process had ended, a thematic analysis based on predetermined themes began [2]. The theme-set used was based on the reflective Cognitive Processes (CP) found in the participants Smartphone use and the Subjective User Experiences (SUE) associated with the actual use [9]. Through physical and visual (not online) ordering of the relations in the data, it was possible to study and discuss which cognitive categories and subjective user experi-

Fig. 3. Then all pieces were analyzed as a collective

Example: Dohn and Johnson describe m-learning strategies and the use of the students' own Smartphones as an advantage. When the students already know the media, they are already competent and can rapidly decode relevant strategies and instead focus on the learning content. They found students use small one-player games, they suggest including these in formal learning applications [3]. But what happens when one adopts the cultures and behaviours of the informal strategies into a formal learning setting? This may be valuable but can also be disadvantageous in some situations. As such this projects mobile probe data also showed use of small one-player games. The probe process, however, disclosed that they were played as a fast game “to kill time”, or while waiting for something else to happen (during transport etc). If designed into learning software, the culture of “beating the game” fast, rather than learning about the domain knowledge, may be inherited.

5 Second Use – Knowledge Sharing in consultancy

This project was conducted in 2011 and it is noteworthy that the consultancy company had not asked in advance for the research to take place, but decided to use a great deal of effort and man-hours, once they were introduced to the ideas (of the whole prephase). The company was in the midst of reorganizing their knowledge sharing platform and had discussed the possibility for mobile support, but had not yet investigated this nor made any decisions regarding this. The total pre-phase was part of the master students’ thesis, and the primary research focus was the mobile probing method and how it worked in a pre-phase.

Prior to the mobile probing process, the potential participants received an introduction to the method and to the investigation at hand. It was the employees nearest manager who decided, who participated. 6 people participated of 9000 employed in the company, making it a truly small, but still interesting insight in to their everyday practices and feelings towards knowledge management. For the mobile probing process a mobile probe guideline was developed, similar to the idea of an interview guide. The
objective was to understand more about these employees everyday knowledge sharing practice and to learn about the terms and phrases they themselves used for processes related to knowledge sharing. The tables below illustrate this point and summarises the number of mobile probes and responses sent.

<table>
<thead>
<tr>
<th>Table 2. Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of tasks sent</td>
</tr>
<tr>
<td>Number of responses received</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Media used in responses*</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMS</td>
</tr>
<tr>
<td>Mail text</td>
</tr>
<tr>
<td>Picture</td>
</tr>
<tr>
<td>Audio</td>
</tr>
<tr>
<td>Video</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Table 3. Example of question and answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hi XXX. Time for thursday last task and the last message you will get from Please tell me about a situation in which input from a colleague changed my work practice. I look forward to getting your responses to thursday task.</td>
</tr>
</tbody>
</table>

It was highlighted to me by a colleague that getting caught up in the old email knowledge share medium was not only clogging up my mailbox but was inefficient. By using SharePoint to upload items, using announcements and simply sending a link in an email should become the norm for everyone. This is now the way I communicate on the UK. |

<table>
<thead>
<tr>
<th>Sent Media/SMS</th>
<th>Received Media/SMS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tech options - social practice - know how - internal knowledge sharing efficiency</td>
<td></td>
</tr>
</tbody>
</table>

In retrospect, when analysing the time of probe distribution, it becomes obvious that the probes consistently was distributed at 9:00, 12:00 and 16:00. Though not an explicit decision, clearly the research team shared a notion on when a probe may be more or less intrusive. Already at day 1, one of the respondent expressed that the probing was a stress factor, responding with a “I am busy these days, so please make it brief”. This adds a layer to the mobile probing process as it took place in this context, where the respondent was more or less chosen by the nearest managers and thus not volunteered. (Which also became part of the analytical discussion.)

To use this insight in the pre-phase project results, the analysis took point of departure in a set of pre-defined themes, derived from the existing data (meeting, materials and observations from the consultancy company). A possible drawback here was an increased risk for contamination of the data analysis, by inducing ones pre-conceptions as they are or have been “built” in the analysis of the other data. The incremental, iterative analysis process, where the raw data is revisited and where the themes are discussed after each cycle (leading to reformulation or even to a theme being discarded), aims at minimize this risk.

Mobile probing is a method that by explicit choice is digital. Nevertheless the analysis process makes use of a physical representation and handling / re-coding process; a process that takes place after all mobile probes are collected. Good network views are available in digital analysis tools as Atlas.ti and NVivo, but the bodily engagement and collaborative dialog while doing so was prioritized here. Soon, technologies may support the analyst in an acquiring equally sense of the data, but for now this was a very adequate process.
6 Discussion of experiences and conclusions

As every respondent participate in parallel at a given time period, the method provides a setting for getting access to people independent of space and time. The probing aspect gives knowledge about what the person is doing, but at the same time makes it possible for the researchers or practitioners to make follow-ups based on previous responses. Questions that arose were: what does this mean - which would lead to an individual follow-up question, and are other people in similar situations - which would lead to a follow-up question to all participants. This mean there is the possibility to work with gaining some continuity by asking every participant the same question in new ways, or new questions all together. This is different from traditional interviews, where the basis of the guide may change over time (as interviews are carried out), though follow-up questions of course can and do take place, it means starting up the relation again. Here, the continuity and changes can happen to every participant during the mobile probe period.

However, it was often difficult to receive in-depth answers. This is likely to be linked to choice of medium (though not directly investigated in these two projects). In particular SMS, but also when answering mails on a phone, which makes the answers somewhat short. There is the same tendency in chat-interviews.

The mobile probing process as used here, made use of a large analytical phase in order to use the incoming data in the design phase, whether for design of products or design of processes. The physical sorting of data, provides the team with a very dynamic and visual representation, but at the same time this process needs logging with pictures or similar, to be preserved. And similar a cloud-based storage solution for the mobile probe materials is essential in, making it possible to gain access to all the material regardless of time and location. This allowed for everyone in the project team to get an overview of all the responses, as they are received, and thereby ensured the qualification of the open and ongoing dialog.

In conclusion, the mobile probing method and the mobile probes used, differ from the existing and original cultural probes in that: During the information gathering process the mobile probes takes use of a qualitative interview-based method, with focus on an authentic dialog. This gives the researchers the possibility to get to know the researchers and the participants the researchers. Through this, the probing method can allow for facilitating the participants, pursue interesting points etc.
Secondly, the mobile probing process used a combined analysis strategy, with predefined themes, allowing the on-going analysis of probes as they were received and then later in a physical coding process as well.

Using mobile probes can be a very rewarding for the projects in term of uncovering non-knowledge, but in some situations the mobile probes are seen as intrusive (understood as too time consuming for user to deal with).

IT frameworks: are they useful or not?

Luis Velhinho, Arminda Lopes
luis.velhinho@gmail.com; aglopes@ipcb.pt
Instituto Politécnico de Castelo Branco, Escola Superior de Tecnologia,
Av. Do Empresário, 6000 – Castelo Branco, Portugal

Abstract. Technologies (IT) Companies’ Frameworks have been one of the solutions for the increasing demand for new products and services that are more and more complex and need to be delivery on the less time possible. This paper presents the work in progress in a master thesis. The goal was to evaluate Frameworks used by business enterprises and to state the advantages and disadvantages in their use. The chosen methodology for data collection and analysis was the Grounded Theory Method from which it was possible to obtain some conclusions based on given answers. With this research, the intention is to present some recommendations for companies that work with this type of products to improve their productivity and profit.

Keywords: Company Frameworks, Content Management, Graphical User Interface, Information Technologies, Work Analysis

1 Introduction

The business market has sought, in last years, to take out advantage of new technologies as a differentiation factor for better productivity and to reach new customers. This increased demand has brought pressure to the suppliers of IT to provide products and services of greater complexity on a reduced time.

The IT companies meet their expectations supported on their customers’ claims, and they found solutions thinking in profit incomes. For many companies one of the ways to be different and to respond to this challenge has been the Frameworks development which allows accumulating knowledge and experience that exist within the company. Conversely, it permits to advance faster with their products.

According (IBM, 1997) “A Framework is a set of blocks of pre-fabricated software that programmers can use to apply, or change specific computing solutions. (…) With the Frameworks the software developers do not need to start from beginning each time they start building an application. Frameworks are built from a collection of objects, so far as the design codes to be reused.”

In this research we try to analyze the impact of these types of tools inside companies, and we will try to understand the following concerns:
• To understand the segment markets where the Companies Frameworks are used furthermore;
• To identify the advantages of using Frameworks for enterprise businesses as well as for the development teams;
• To understand the decision factors considered for the choice of a framework and the customers’ satisfaction;
• To detect key requirements in the creation of Frameworks;
• To identify areas of improvement on the Frameworks.

2 Frameworks

According Sauvé (2012) frameworks can be classified according to two dimensions: where the framework is used and how it is used. And they can be regarded in three distinct ways:

• White-Box - where the developer modifies or extends existing functionality by defining or overlapping methods.
• Black-Box – where the developer uses functions already presented in the Framework (the internal modules of the Framework cannot be viewed or altered and interfaces already defined must be used).
• Hybrids – has the same behavior as the White-Box and Black-Box

Frameworks are used by companies with different goals. It depends on the type of use that the company intends to do, in some cases, they only intend to have a tool that helps in a simple project’s development, but in other cases, they intended to develop a tool that has a huge amount of data and logic definitions.

2.1 Framework Wizy

Wizy is an agile development Framework that we use within the enterprise. It enables rapid creation of web applications based on web front ends, figure 1. It was created as a platform to allow fast development of multiple application projects. Conversely, it offers an entire multi-runtime application with embedded functionality for content management and workflow. The dispersed data is aggregated in a standard manner allowing content management in a flexible way, providing libraries and components that let prompt development for custom applications.
Typically, a framework is composed for several organizational layers that allow a higher abstraction for anyone working with the Framework.

Figure 2 presents an example of the Framework Wizy structured on 4 layers. The first layer, External Systems, is the whole systems that interact with Framework. The second layer, Content Provider, provides interfaces to interact with internal and external systems. The third layer, the Content Aggregation, is where all contents are aggregated into one default or custom ASPX page. The last layer Content Presentation is shared between Server and Client: the server sends the page on XML and applies XSLTs and CSS styles. The client browser interprets the whole data and shows the page to the user.
3 Research Methodology and Methods

Grounded Theory Methodology was developed by Glaser & Strauss (1967). It is a general methodology for developing theory that is based on data systematically collected and analyzed (Strauss & Corbin, 1994). Grounded Theory (GT) is a general method to use on any kind or combination of data, and it is particularly useful with qualitative data (Glaser 1998).

The main goal of this approach consists of a set of steps which will “guarantee” a good theory as the outcome. It involves two phases in the analysis of qualitative data. Data fragments are compared in order to derive concepts and categories which catch their analytically relevant properties. The second phase is used to elaborate, refine and reduce results of the first phase.

3.1 Research Methods

This research was prepared for business companies which mission is to invest in software development for clients who wants customized applications to manage and improve their business.

This study was conducted through the use of different research methods. Data was collected from staff interviews, observations, and surveys. Interviews were conducted with staff from 11 Portuguese companies whose core business was IT consultancy operating in several target markets with over 5 million euros.

Interviews were face to face on a private room and with the interviewees’ authorization they were audio recorded. Later, a transcript of the interview was made. Based on a script several questions were asked and the researcher took also some notes.

Finally, an anonymous online survey for IT developers was made through programming forums, social networks, e.g. LinkedIn. The forum’s participants were about developers that work with multiple Frameworks.

4 Work Analysis Procedures

The main motivation of this research was the researcher’s concern about several rejected projects from customers at the end of an order. The intention was to try to understand and find out the reasons that led projects to this end.

This research was carried out through several phases. Initially, we started reading literature, namely, Fayad (2006) and technical documentation about object-oriented application frameworks. Following Charmaz (2006) when applying GTM preconceived conceptions should not be feared but instead serve as a starting-point for looking at data. After this initial data collection and analysis phases, we decided to make interviews. Interviews permitted to have rich data through a constant comparative method which constitutes the core of grounded theory, ideas started to be organized but needed to be validated. To validate the analyzed data and to keep the GTM process of constant comparison analysis, we decided to do an anonymous online survey.
Several IT companies were invited to collaborate in completing the survey. Fig. 3 presents the several phases for data collection, analysis and comparison.

Fig. 3. Research Methodology Phases

On Phase 1 bibliography search and reading are the main objectives for data collection GTM process; after bibliography chosen we passed on Phase 2 where the interviews were prepared and completed to collect data for the analysis. The data was compared with the previous bibliography and the online surveys were prepared for data validation one phase 3. Phase 3 also includes the data analysis and data and comparison with that of other phases.

On Phase 4 we start to understand the theories emerged from the data analysis.

Based on the literature, different set of profiles were identified to establish a set of questions according to interviewees’ experience. After face-to-face interviews, we did memo-writing which has high priority in the process of constructing a grounded theory. Memo-writing is, according to Charmaz, the pivotal step between data collection and the draft. When an idea was got, “It prompts you to analyze your data and codes early in the research process” (Charmaz 2006:72).

Interviews demanded a preparation process before: background information about Companies’ Frameworks were collected through books and internet articles which permitted to understand, as well as, to describe Frameworks’ components and the way
they work. The researchers also took in consideration around six years of experience in one of this kind of companies.

The reading and note taking processes about frameworks led to a spreadsheet elaboration with some questions that should be asked to interviewees. It was realized that their different profiles required different forms of questions. A developer, for example, sees the Framework on a different way that a supporter or an architect do.

Defined the profiles and questions meetings were scheduling with all the persons. It was decided to start with some of researcher’s colleagues to get more experience and to help in the questions’ redefinition.

When the interviews were concluded a new phase arose, the data transcription and analysis. From that moment, different codes were defined to give rise to several categories. This analysis process was made with other spreadsheet and from there charts and diagrams were constructed. Fig. 4 summarizes the work analysis during data collection and analysis phases.

  - Frameworks are useful for IT Companies

**Fig. 4. Data Collection and Analysis Process**

Fig. 5. presents an example of data analysis for one of the answered questions by interviewees.

**Question:** What are the advantages of using Frameworks by business enterprises?
5 Results and Discussion

After data analysis it was found that business sectors that most use Companies Frameworks are those of Telecommunications and Media, High Tech, Financial Services and Public Administration as shown in Figure 6.

About 89% of respondents have worked with a Framework and from these 43% have between 6 and 10 years of experience.

The benefits for developers who have worked with the frameworks are among others the speed of implementation, structuring, reuse and efficiency. The major identified drawbacks are the lack of documentation and the costs of introducing new features as well as versatility of the Framework in accordance with certain customer requirements.
For companies, the most obvious advantages are the productivity increase associated with a shorter development time, higher profitability and the creation of standards inside the company.

Some key factors to the creation of Frameworks were also identified: formation, implementation speed, performance and security. It was interesting to see that the average investment by companies on these products is between 10% and 15% of the budget.

From the interviewees’ responses it was considered that the support for multiples systems is a challenge for the future, side by side with the versatility and adaptability, and also the continuous evolution and the introduction of new features in the framework.

The companies that are betting on this type of product, a framework, although they are achieving great profitability, they need to do some more work concerning new solutions to their customers.

6 Conclusions

This research was important and it permitted to have some answers to the initial questions from the interviewees and from the online survey.

The data analysis showed that there are some activity sectors that invest more in this type of products than others, for example, the Telecommunications’ sector.

Many users highlighted some key attributes on the advantages of using Frameworks like: time development reduction and the increase of profitability.

Two of the major evident concerns are the lack of documentation and learning courses. On these areas companies need to do some effort to improve the quality of utilization of the Framework.

Answering to the title question of this paper it can be argued that Frameworks are useful for companies. They allow to reduce costs and increase productivity, besides allowing to offer new and innovative products to its customers.
